The following appointments are announced:—Surgeon-Captain F. W. Gee (Bengal), Medical Officer of the 5th Bengal Cavalry, to the Medical Charge of the Bundelkhand Political Agency; Surgeon-Captain F. P. Maynard to act as Resident Physician, Medical College Hospital, and Professor of Pathology, Medical College, Calcutta until further orders; Surgeon-Captain J. Chaytor-White, Officiating Civil Surgeon, at present attached to Allahabad, to the Civil Medical Charge of the Unao district; Surgeon-Captain J. M. Crawford, Officiating Civil Surgeon, to officiate as Superintendent, Central Prison, Benares; Surgeon-Captain H. C. Thurston, A.M.S., doing duty at the Station Hospital, Bangalore, to the Medical Charge of the Cantonment Hospital, Bangalore; Surgeon-Lieutenant H. A. Hinge, A.M.S., to do duty in the Belgaum and Bangalore districts, and Surgeon-Lieutenant W. D. Erskine, A.M.S., to do duty in the Madras district. Surgeon-Captain W. R. Edwards (Bengal), Civil Surgeon at Quetta, is granted furlough for one year and fourteen days. Surgeon-Lieutenant-Colonel W. E. Griffiths, 20th (the Duke of Cambridge's Own) Punjab Regiment, is granted leave for one year; Surgeon-Lieutenant-Colonel B. Evers, Civil Surgeon, Raipore, is also granted leave for one year. Surgeon-Captain F. J. Drury, Resident Physician, Medical College Hospital, and Professor of Pathology, Medical College, Calcutta, is allowed furlough for fifteen months.

ARMY MEDICAL STAFF.

Surgeon-Major-General Alexander F. Bradshaw, C.B., is placed on retired pay. The following appointments are notified:—Surgeon-Colonel Albert Augustus Gore, M.D., F.R.C.S. Irel., to be Surgeon-Major-General, vice A. F. Bradshaw. Brigade-Surgeon-Lieutenant-Colonel William Taylor, M.D., to be Surgeon-Colonel, vice A. A. Gore. Surgeon-Lieutenant-Colonel James Albert Clery, M.B., to be Brigade-Surgeon-Lieutenant-Colonel, vice W. Taylor.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Staff-Surgeon Christopher Pearson and Surgeon Arthur Gaskell to the *Retribution*.

ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned Surgeon-Captains have been appointed Surgeon-Majors:—Edward Williams and Francis J. Walker. Surgeon-Major Charles E. Abbott having resigned his Volunteer appointment, ceases to be an officer of the Army Medical Reserve of Officers.

VOLUNTEER CORPS.

Artillery: 1st Norfolk (Eastern Division, Royal Artillery): Surgeon-Lieutenant A. H. Jackson resigns his commission.

Note: 1st Nottinghamshire (Robin Hood): Surgeon-Lieutenant H. G. Ashwell has been appointed Surgeon-Captain.

THE LATE LOSSES IN THE SERVICES.

Death has been very busy of late with notabilities in the services. The navy has lost Lord Alcester, so long known as Sir Beauchamp Seymour, upon whom, when of the rank of Admiral, the duty fell to carry out the bombardment of Alexandria and the operations in Egypt with which his name is associated. A veteran soldier of long and distinguished service—in India especially—full of years and honours, Field-Marshal Sir Patrick Grant has just been interred with a great military gathering of Field-Marsals and others at his funeral. Sir George Chesney, who saw active service during the Indian Mutiny and was wounded at the siege of Delhi, but who was better known to the public as the author of "The Battle of Dorking," "Indian Policy," and several other works, has died quite suddenly from angina pectoris. The deceased general, who was a man of undoubted ability and an admirable writer, held numerous important appointments in this country and in India, and was an M.P. for Oxford. He was not altogether free, perhaps, from some prejudices about medical officers, but he was, as we happen to know, nevertheless very friendly and kind to some of them. Lastly, in these days, when success does not by any means invariably attend ability, merit and integrity, we have to record the death of Sir Charles Mills, a really able and deserving man, whose early career was a military one, and who by his talent and energy rose to the high and important colonial appointment which he occupied at the Cape, and subsequently in this country.

ARMY MEDICAL SCHOOL, NETLEY.

The seventieth or summer session of the Army Medical School commenced on Wednesday, April 3rd. The session is attended by thirty surgeons on probation, twelve for the Army Medical Staff, and eighteen for the Indian Medical Service. The following are lists of the surgeons on probation:—

ARMY MEDICAL STAFF.

- | | |
|--------------------|-----------------------|
| 1. L. F. Smith. | 7. G. T. K. Maurice. |
| 2. S. H. Fairrie. | 8. F. E. Gunter. |
| 3. R. J. Blackham. | 9. J. H. Campbell. |
| 4. J. V. Forrest. | 10. J. Grech. |
| 5. H. W. Grattan. | 11. P. Dee. |
| 6. E. Fawcett. | 12. E. G. E. O'Leary. |

INDIAN MEDICAL SERVICE.

- | | |
|----------------------|-----------------------|
| 1. J. Stephenson. | 10. R. F. Standage. |
| 2. F. N. Windsor. | 11. F. L. Blenkinsop. |
| 3. P. F. Chapman. | 12. J. E. Watson. |
| 4. W. B. Turnbull. | 13. H. A. F. Knapton. |
| 5. A. Hooton. | 14. C. G. Webster. |
| 6. J. M. H. MacLeod. | 15. A. A. Gibbs. |
| 7. E. E. Waters. | 16. A. Moore. |
| 8. A. Leventon. | 17. G. E. Bensley. |
| 9. A. F. W. King. | 18. E. M. Hiewicz. |

SURGEON-MAJOR G. S. ROBERTSON, C.S.I.

Surgeon-Major George Scott Robertson, C.S.I., the British Resident at Chitral, belongs to the Bengal Medical Department, which he joined in 1878. As a young officer he took part in the Afghan War, and the operations around Kabul. He has since been employed in the Foreign Department, and was mentioned in despatches for his services as Chief Political Officer with the Hanza-Nagar Expedition of 1891-92.

THE GREENWICH HOSPITAL PENSION.

The Greenwich Hospital Pension of £50 a year for Fleet and Staff Surgeons of the Royal Navy, rendered vacant by the death of Deputy Inspector-General David Lyall, M.D., has been awarded to Deputy Inspector-General William Ross, M.A., M.D.

The s.s. *Britannia* brought 278 patients to Netley from India on the 27th ult.

POPULAR HOSPITAL FOR ACCIDENTS—The annual meeting of this charity was held in the institution at Blackwall on March 26th, Mr. John Coles presiding. The report stated that an entirely new hospital, containing sixty-four beds, was now completed, and that the old building had been converted into a residence for the medical and nursing staff. The cost of the new structure had been £30,900, and something still remained to be done, as a new operating theatre, mortuary, and post-mortem room were urgently required. The total number of accidents treated during the past year was 8276, of which 3166 occurred in the patients' homes, 2415 at work, and 1720 in the streets. The working men of the district had contributed £650 during the year, and Sir Donald Smith had given £1500.

Correspondence.

"Audi alteram partem."

"THE WOMEN'S FREE HOSPITAL, SOUTHAMPTON."

To the Editors of THE LANCET.

SIRS.—Dr. Elliot and I offered months ago, when the affairs of this young institution first attracted the invidious notice of Mr. Frederick John Palfar, to read a paper to the society on the complete work of the hospital, but the offer was not accepted. Surely if their desire had been one for real inquiry and for instruction in righteousness, no committee could have been more after their own heart or more after the customs of our profession. After the refusal of such an offer, I regarded their commotion as merely a personal attack on Dr. Elliot on account of his professional success—"because he drives a pair," as one of them frankly confessed, as the chief cause of it—and I did not trouble any more about it. Dr. Playfair's action has been hasty and unfair.

I am, Sirs, yours faithfully,

Birmingham, April 3rd, 1895.

LAWSON TAIT.

* * Mr. Lawson Tait has hardly realised the importance of the statement made by the secretaries of the Southampton Medical Society. Mr. Elliot has sent us copies of all the correspondence that has passed between the Free Hospital for Women and the Southampton Medical Society, and it is his intention, or that of the hospital, we understand, to reply in detail.—ED. L.

"THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED."

To the Editors of THE LANCET.

SIRS.—Now that you have again opened your columns to the discussion of the question of fees in the letters concerning the London and Manchester Industrial Society there seems to be a chance that we may arrive at the actual facts of the matter and be able to deduce from them what is a right and fair price at which a medical man may undertake to treat his poorer neighbours. If this right standard of remuneration is once established we could by a united effort put an end to the system of sweating under which many of us now work. I think I am right in saying that 1s. a quarter for each adult is the usual fee that obtains in nearly all the better-class clubs. Although this may seem very little it still may be a fair contract fee; we none of us feel we are sweating a fire insurance company by paying the small sum of 3s. a year to insure us against loss by fire to the extent of £100. However, I think I shall be able to show that in the case of sick insurance 1s. a quarter is not a fair premium to pay. In the report of the Hearts of Oak Benefit Society for the year 1892 I find the amount of sickness amongst its members for that year works out to one member out of every thirty-seven being permanently on the funds of the society. This does not give us an exact account of the number of members applying for medical treatment, as some would keep at work although under the care of the medical officer; so that we may take it that about one member out of every thirty is constantly in receipt of medical treatment. This would give us a payment at the rate of about 2s. 4d. a week for each member who is constantly sick. Can we call this a fair rate of payment? I think, Sirs, you will agree with me that it is not. I would suggest that, taking an average between the slight cases of sickness requiring little or no attendance and the severe cases requiring constant care, 5s. a week would not be too much to ask, which would be covered by a payment of 2½d. per member per week. It was very noble of the South-West London Medical Society to pass a resolution condemning 1s. and 1s. 6d. fees, but if the members of this society are practising in poor neighbourhoods and have never soiled their hands with shillings they have not only been foolish but cruel, driving poor and honest patients into the hands of the dispensing druggist and the cheap and inefficient dispensary. We must always recognise the fact that a shilling means a great deal to a man with a wife and family when he is only earning £1 a week, and what we want is not a fixed fee, but as much as the patient can honestly afford to pay us.

The 1s. fee can never be abolished until what is already indicated by the great elasticity of our fees is officially recognised and the rich are made to pay for the medical attendance on the poor, or, in other words, we are supported out of the rates.—I am, Sirs, your obedient servant,

WILLIAM F. CLARKE, M.B., B.S. LOND.

Fulham, S.W., April 1st, 1895.

To the Editors of THE LANCET.

SIRS,—The statement which Mr. Woodward, managing director of the above company, makes without "hesitation" is, no doubt, a *bona fide* one; and his error is pardonable, seeing that he is not in a position to express an opinion on the somewhat complex question of the remuneration of medical men. It is certain, however, that what he ventures to state—viz., "On the question of payment to our medical officers we have no hesitation in saying that they are as well remunerated by us as by their private practice amongst the same class of people"—is disproved both theoretically and practically as a matter of common notoriety amongst medical men. In the first place, it is disproved theoretically because it is perfectly obvious that the system of canvassing patients and offering them medical attendance without medical examination for a sum which does not exceed 4s. per annum must necessarily act as a strong incentive to induce many patients to join who have at least remunerated medical men with a few pounds annually, and who could certainly pay more in private practice than they do under the company. It may be asked how it is that innumerable old-established practitioners can persuade themselves that it is to their private interest to accept this work, seeing that the system of touting from house to house is, to say the least, calculated to educate the public to the too-prevalent idea that a professional man is in a pecuniary sense on a par with an ordinary mechanic.

I am, Sirs, yours truly,

Queen's-road, April 2nd, 1895.

CLEMENT H. SEERS.

To the Editors of THE LANCET.

SIRS,—As a discussion is now going on in your columns concerning the London and Manchester Assurance Company I beg to enclose you a list of the medical referees (over one hundred in number) for South London. Many of these gentlemen have good-class practices and would look down upon those of their brethren who charge low fees. But surely it is more honourable to charge sixpence or a shilling for advice and medicine than to be a medical officer of the above company. I am certain that much harm, in a monetary sense, is done to the profession by this society, as most of those who belong to it could well afford to pay a medical man.

I am, Sirs, yours truly,

H. DE BURGH DWYER.

Blackfriars-road, S.E., March 30th, 1895.

To the Editors of THE LANCET.

SIRS,—I shall be glad to hear how Mr. W. Woodward, managing director of the above-named company, explains the following advertisement, which appeared in the *Derbyshire Courier* of March 30th, 1895: "Medical aid in all districts within ten miles of Chesterfield. For terms apply to Mr. Woodger, 9, Marsden-street, Chesterfield." Now, Sirs, the name and address given in this advertisement are those of the local agent of the London and Manchester Assurance Company. I can hardly think the company would be so anxious to further the Medical Aid Branch if there were no profits to be made out of the working of it.

I am, Sirs, yours faithfully,

April 2nd, 1895.

ONLOOKER.

To the Editors of THE LANCET.

SIRS,—The managing director of the London and Manchester Industrial Assurance Company has carefully avoided referring to the most objectionable feature in the working of his company—viz., that of "touting" for clients. I speak from personal experience and not from hearsay evidence, and I assert that the agents of the company make a house-to-house canvass and admit anyone who is willing to pay the necessary fees. Some time since I had reason to regret the loss of two patients—for a short time, fortunately—who had been inveigled into joining this company. So strong is the feeling in this town against the company's

mode of proceeding that the Cardiff Medical Society determined some time since not to admit any gentleman as a member of it who held an appointment under this or any similarly conducted company. It is to be hoped that the *modus operandi* of this company and of all such-like companies will be brought under the notice of the General Medical Council at their next meeting.

I am, Sirs, yours truly,

MEDICUS.

Cardiff, April 2nd, 1895.

To the Editors of THE LANCET.

SIRS,—Mr. Woodward, the managing director of the London and Manchester Industrial Assurance Company, ignores the gravest of the charges brought against his society. As I stated in my former letter, if medical men estimate their capabilities at 2d. or (as you corrected me) 1½d. per week, there is nothing to prevent their contracting to give their valuable aid at that remuneration and at the same time lowering their profession by so doing. What I strongly objected to was that the members of an honourable profession should tacitly sanction the touts of the society annoying the patients of other practitioners (who value their skill at higher remuneration) by pestering their patients to join the society and place themselves in the hands of the medical men sweated by this society. Will Mr. Woodward deny such procedure or will he plead ignorance of the action of his touts? In the former case I am prepared to bring proofs of my statement, and beg to inform him that these agents do not confine their attentions to persons of "meagre incomes" or to those who are unable to pay properly for skilled advice.—I am, Sirs, yours obediently,

April 1st, 1895.

A GENERAL PRACTITIONER.

THE SAC IN EXTRA-UTERINE PREGNANCY.

To the Editors of THE LANCET.

SIRS,—In the report of my remarks on Mr. Sutton's paper, read at the Medical Society of London, it is stated that I "asked why there was so much bleeding from a small ruptured tubal sac," and that recently when I was "operating on such a case the blood spouted out furiously, but in that instance a band passed from the vermiform appendix to the sac. The band was found in reality to spring not from the appendix itself, but from its mesentery, and the bleeding came from an artery in this." I fear that I failed to make myself perfectly clear. What I intended to say was that the arteries in a tubal sac bleed very freely and the hæmorrhage does not tend to stop spontaneously. The vessels in adherent structures outside the sac, on the other hand, do not seem to share in this undesirable peculiarity; indeed, they do not bleed more than in adhesions to malignant pelvic tumours. In my case the blood spouted freely from a slight tear which I made on the surface of the tubal cyst, but there was no difficulty in securing the vessels of the pedicle. The only trouble arose from the artery of the appendix, which happened to adhere, with its mesentery, to the sac, as is often the case in pelvic tumours. This artery and also the vessels in the pedicle were in no sense diseased through communication with the vessels in the sac.

I am, Sirs, yours faithfully,

ALBAN DORAN.

Granville-place, Portman-square, March 29th, 1895.

THE SPREAD OF TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—Some four years ago, and on more than one occasion since, I drew attention to the probable diffusion of typhoid fever into the houses along the route of the sewers leading from large hospitals and similar institutions, where numbers of cases of this disease were treated, and where, as too frequently is the case, no attempt, or at least an inefficient one, was made to disinfect the dejecta. I proposed at that time that the dejecta should be destroyed by fire, and not permitted to specifically infect the sewage. That suggestion has already been carried out in more than one institution. That typhoid dejecta is frequently not disinfected thoroughly I have found to be the case in many hospitals; that these dejecta are the main source of infection, and that the bacillus,

¹ THE LANCET, March 30th, 1895.

though difficult to isolate in sewage, will live at least some days in such surroundings, has been abundantly shown. These questions have all been frequently and so recently discussed that I need not enter into them at the present time; but I have been for years anxious to know whether the incidence of the disease shows any increase in the houses along the route of the infected sewage coming from such institutions compared with the rest of a town or city. This could easily be mapped out where notification of typhoid fever was in force, and where a map of the town sewers showing the direction of the currents was obtainable. Both these conditions are generally available. I have myself tried and am at present engaged in dotting such a map of the sewers coming from the Dublin hospitals that receive typhoid fever cases. The chief object of this communication is to ask fellow workers to do the same where available elsewhere. The value of such map demonstrations, were a number to agree, showing the increase in such houses or otherwise, is self evident. Even supposing no such increase was shown, still it would be necessary to destroy the typhoid dejecta to prevent the possible and common spread of the disease by the dejecta finding its way into the water for domestic use. I should be glad to hear if any investigations on the lines I have proposed have been carried out by medical officers of health. The question whether other diseases spread in a similar direction might be a subject of future investigation.

I am, Sirs, yours faithfully,

ANTONY ROCHE, M.R.C.P. (Irel.).

Professor of Hygiene, Catholic University
Medical School of Dublin.

Stephen's-green, South Dublin, March 27th, 1895.

TUMOURS OF THE SUPRA-RENAL BODIES.

To the Editors of THE LANCET.

SIRS,—In treating of the liability of any part of the body to originate neoplasms, it is of primary importance not to neglect perspective. I am induced to make this remark because on reading your report of Dr. Rolleston's lecture on the Supra-renal Bodies, it seems to imply that neoplasms of these structures are fairly common. This of course may merely be an instance of the many erroneous impressions that necessarily ensue from the modern mania for abbreviation. However, on looking over the chief monographs on the supra-renals I have found that they convey a similar implication. Hence it seems to me important to call attention to the fact that it is an occurrence of the greatest rarity for any kind of neoplasm to arise from the supra-renal bodies. Of 13 824 primary neoplasms consecutively under treatment at four large London hospitals, I found only one instance of the kind recorded—an adeno-sarcoma. Similarly, Gurli's analysis of the localisations of 13 971 primary neoplasms—under treatment at the three chief Vienna hospitals—does not contain a single instance of supra-renal neoplasms. The truth is that obsolete structures like the supra-renals, vermiform appendix, male mammae, os centrale, sesamoid bones, clitoris, uterus masculinus, thymus, inter-vertebral discs, membrana nictitans, coccyx, &c., have but an exceeding small tendency to take on the neoplastic process.—I am, Sirs, yours truly,

Preston, March 28th, 1895.

W. ROGER WILLIAMS.

"PLEURITIC EFFUSION WITH NEGATIVE PRESSURE IN THE PLEURA."

To the Editors of THE LANCET.

SIRS,—The problem presented by Dr. West under the above heading, of which I ventured to attempt an explanation, has now been declared by him to be of the nature of an elementary fact, and we therefore agree in regarding the existence of a negative pressure as the normal condition in the first stage of effusion. He still considers, however, that this negative pressure rapidly diminishes as the fluid increases in amount, and that, therefore, the explanation I gave will not apply to the case he reported, and is in fact "actually erroneous." On the other hand, I hold that the negative pressure diminishes slowly or rapidly according to the rate at which the fluid is effused, and its degree depends upon the amount present, and it disappears only when the quantity exuded is very large. This stage of the disappearance of negative pressure in fluid effusion is marked clinically, according to Dr. Douglas Powell,¹ by the dulness mounting up above the third cartilage

and by the loss of Skodaic resonance. There were no signs in Dr. West's case that this stage was reached, but on the contrary there was distinct evidence that the effusion was moderate in amount, as shown by the absence of dyspnoea ("respiratory oscillation half an inch"), the entrance of air from the outside, and the failure to obtain fluid from the chest even when the syphonage action of a long tube was employed. Under these circumstances I still think that the amount of the negative pressure, although undoubtedly "considerable," was by no means such as to be incapable of explanation. I am afraid, however, that it is impossible to satisfy Dr. West. When he has propounded an "almost inexplicable" problem, and I have added that according to the teaching of most of the text-books it is altogether inexplicable, he asserts that I am very unfair to the teaching of the present day. Some years ago, while investigating the subject of pleural effusion, I formed the opinion that the importance of the elasticity of the lungs in connexion with the diagnosis and treatment of pleurisy was not fully appreciated by most of the leading teachers—e.g., Wilson Fox, Fagge, and Clifford Allbutt. That, of course, was merely an opinion, which I have supported in several papers published in THE LANCET,² and in stating these views I have always acknowledged my indebtedness to what I consider the sound teaching of Dr. Douglas Powell. But in adopting, and I hope supporting, Dr. Powell's teaching I have made no imputation against those who interpret the facts differently.

I am, Sirs, yours faithfully,

Carlton-hill, N.W.

G. A. SUTHERLAND.

"THE TITLE OF 'DOCTOR.'"

To the Editors of THE LANCET.

SIRS,—Re the title of "Doctor," it is interesting to note that in "Tristram Shandy" Slop the apothecary is entitled "Doctor," also that "Peter Pindar," himself an M.D., in one of his poems makes a servant girl speak of the family practitioner as "old Doctor Slop." It is thus evident that a hundred years ago and more the title of "Doctor" was, rightly or wrongly, popularly accorded to the general practitioners of the day, a class of men far inferior in education and social position to those of our day. Customs of such antiquity die hard, and, whatever we may call ourselves, we shall for a very long time be "Doctor" with the public. This custom must necessarily involve a certain amount of injustice on all sides; but perhaps the most glaring injustice is that a man can obtain a degree from a university entitling him to call himself "Doctor" after passing examinations not one bit better than, if as good as, those necessary to obtain the London double qualification which gives no legal right to the title. Unless some reform is shortly introduced this must surely tell seriously against the London corporations and schools, as I imagine that, like myself, most people, in the event of their sons going in for the profession, would send them to a university where they can obtain all the necessary qualifications to practise, and at the same time acquire a legal right to the title of "Doctor," in preference to sending them to study in London, where they cannot obtain that privilege.

I am, Sirs, yours faithfully,

Dawlish, March 31st, 1895.

A. DE W. BAKER.

"PROVISION FOR YOUNG IMBECILES."

To the Editors of THE LANCET.

SIRS,—I am unwilling again to obtrude myself upon your readers, but the publication since I wrote to you last week of a Parliamentary return as to the number of imbecile and epileptic children in workhouses (briefly referred to on page 847 of your last issue) seems to call for some additional remark. I have no fault to find with the form of the return, which is satisfactory, inasmuch as it shows that the Local Government Board is paying attention to the necessities of the case; but I venture to suggest that the numbers given in the summary by no means adequately represent the extent of special provision which it is desirable to make for pauper imbecile children. It is not only the children of this class now actually in workhouses that must be taken into account—there are many others residing with relatives who receive out-door relief for their maintenance. There are, moreover, a considerable contingent of imbecile children in the various county lunatic asylums, mixed up (for the most

¹ Diseases of the Lungs and Pleura, fourth edition. 1893, p. 107.

² The Physics and Diagnosis of Pleural Effusion, July 22nd, 1893, and the Treatment of Empyema, Jan. 27th, 1894.

part) with the insane adult inmates, to the disadvantage of both. In addition, there may be found in every county in the dwellings of the poor children of this class in no way officially registered, even if known to the school attendance officers. Their parents would be glad to avail themselves of a rate-aided institution competent to give suitable training to these exceptional children, whose education ought to be a matter of concern to the State quite as much as that of ordinary children or of those who are blind or deaf. The experience of the managers of the Metropolitan Asylums District Board in the matter of providing for imbecile children may be usefully considered in this connexion. Starting originally (in 1874) with 100 children, they soon found it necessary to provide for 250 undergoing training and education, and when plans were made for a permanent institution it was thought that accommodation for 500 would be ample for the needs of London; but when the benefits of the special training given at the Darenth schools became known amongst the poorer classes the demand for accommodation steadily increased, and the provision of 1000 beds at the present time is scarcely adequate. Taking the pauper population of England and Wales at about seven times that of the London district—a ratio also subsisting between the respective gross populations—we find that if accommodation were provided throughout the country in the same proportion as at Darenth an aggregate of 6000 beds would be required independently of the metropolis. In conclusion I am tempted to say, with sincere respect for the many excellent qualifications of workhouse medical officers, that my experience leads me to think that their opinion as to whether or not an imbecile inmate "would be likely to be improved by special training" is not always to be relied on, the question being one for an expert acquainted with the peculiarities of the imbecile class and the results achieved by appropriate modes of education.

I am, Sirs, yours faithfully,

G. E. SHUTTLEWORTH,

Late Medical Superintendent, Royal Albert Asylum,
Lancaster.

Richmond Hill, April 1st, 1895.

"A CASE OF ENCYSTED EMPYEMA."

To the Editors of THE LANCET.

SIRS.—Will you permit me, though late, to correct an error in the report of my case of encysted empyema upon the internal surface of the right lung in THE LANCET of March 9th? On p. 620, fourth line from bottom of first column, "there were signs of *pericarditis*" should read "*peritonitis*, with effusion." So many of the deaths after operation for empyema are caused by suppurative pericarditis that it was carefully sought for during life in the case described, but the heart was normal in site and sounds. The peritoneal effusion was obvious.

I am, Sirs, yours faithfully,

T. CHURTON, M.D.

Leeds, April 2nd, 1895.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary Question.

THE progress made towards the definite step deciding the future of the infirmary is slow; but there may be some advantage in this. Two schemes have been voted on by the trustees—that of the board of management, which was to throw out wings on each side of the present building; the other, moved by Dr. Brockbank, advocated the gradual rebuilding of the infirmary on the present site. Out of the 1300 trustees about 600 recorded their votes—three to one being in favour of rebuilding. An adjourned meeting was held on the 26th ult. to further consider the various proposals for extending the building. Alderman King proposed an amendment to Dr. Brockbank's scheme, which had become the substantive resolution, to obtain the accommodation required by raising the roof and putting an additional story on the present building. This was defeated by a large majority. Sir John Harwood gave notice of another amendment, which was, however, withdrawn in favour of one moved by Dr. Leech. It is, however, worth placing on record: "That the infirmary building remain as it is at present, with such improvements and sanitary alterations as may be found

necessary and desirable. That the stone-work outside the building be cleaned and put into thorough repair, and that only such additions be made to the building as the board may consider necessary in order to bring the whole structure into harmony with modern sanitary requirements, and the providing of such other conveniences as have been adopted in recent institutions of this character." This was withdrawn, however, and Dr. Leech's amendment, "That before proceeding further, a committee, consisting of the members of the infirmary board and an equal number of trustees who are not members of the board be appointed to report on the best means to be adopted for increasing the accommodation afforded by the institution." It was further resolved that the members of the committee outside the board of management should be nominated by the chairman of the board, the Lord Mayor, and the President of the Chamber of Commerce. So the matter stands for the present. The great majority of the infirmary staff favour the complete, but if necessary gradual, rebuilding on the present site. One or two wish for a supplementary hospital as near as may be to Owens College, and confessedly in its interests. No arguments, however, can do away with the fact that the present infirmary, in a central and hence most convenient position, is salubrious, and that there is a prestige connected with it which would be lacking in a suburban annexe. It is to be hoped that the ultimate decision will be to rebuild on the present site. As time goes on, Owens College may be in a position to provide a hospital with its own funds.

Popular Views on Medical Education.

The controversy on infirmary matters has brought to light views as to medical education, that most of us fondly supposed were out of date and exploded. The *City News*, however, which is usually considered an intelligent paper, at once disabuses our minds. It says: "Whilst there are only between two hundred and three hundred in-patients of the infirmary, it appears that no fewer than four hundred medical students are in attendance"; and then goes on to ask, "For whom is the infirmary maintained, for the patients or to give eleemosynary medical instruction to young fellows qualifying for the profession?" It considers, also, that Dr. Renaud ruined his case by telling the meeting that the extensions were required "more for the accommodation of the increasing number of medical students from Owens College than for any other reason," and it quotes, evidently with approval, a dictum Sir John Harwood uttered in 1892: "If ever it got abroad that the infirmary was a school for young students and not an infirmary, it would decline. People would not go to get their maladies healed and their bones set by learners." Such observations as these make one wonder at the tenacity with which ignorance maintains its ground even in the mind of an able man. With the true facts before him no one would see more clearly than Sir John Harwood the great advantage of a teaching hospital to the patients themselves.

Chief Constable's Report.

We are so apt to hug ourselves complacently on the gradual diminution of crime and improvement of morals, in consequence of the spread of Board schools and other elevating agencies, that the recently issued report of the Chief Constable is not pleasant reading. During the past year there has been an increase of 356 in the number of indictable offences reported to the police, the total being 3279, as against 2923 last year. This increase is spread over all classes of crime, but is more particularly marked in housebreaking, breaking into shops, and in cases of larceny. There has also been an increase in the number proceeded against for non-indictable offences of 1412, chiefly for "drunkenness" and "offences under the Vagrancy Act." The total number of persons arrested for all offences was 17,250—11,344 males and 5906 females—and of this number 5260 males (or 46.3 per cent.) and 2973 females (or 50.3 per cent.) were drunk when taken into custody. Many of those arrested for drunkenness had frequently been in custody for the same offence; 62 persons had been arrested more than 20 times, 19 more than 50 times, and one confirmed inebriate has been before the magistrates 193 times. It is quite clear that the present mode of dealing with drunkenness is a failure. The increase is not due to greater facilities for obtaining drink, as there has been a net decrease of 20 licences, the number of public-houses now being 519, and of beer and wine houses 2506. During the year 851 violent deaths occurred in the city, 98 of them being those of babies. This shows that there is much waste of child-life here, as

does also the fact that inquests were held on 318 children under the age of ten. It is noticeable that of these 175 were insured. It is a regrettable fact that 758 juvenile offenders were arrested during the year, 655 male and 103 female. Of these, 57 boys and 24 girls were under ten years of age, while 598 boys and 79 girls were from ten to sixteen years old. It is to be presumed that they either escaped from any education or that the lessons of conduct no doubt given along with the three R's were obliterated by home influences or their social surroundings. It is sufficiently evident that there is still room for improvement in our morals and manners.

A Jurymen on the Drink Question.

At the coroner's court the other day a verdict of accidental death whilst under the influence of drink was returned in the case of a man who fell backwards down some steps and was killed. He had had four pints of beer and an unknown share in a quart of hot whisky which was handed round the beerhouse. Mr. Smelt said "he was sorry there was no power to punish licence-holders for making people drunk and thereby probably causing their death. In such cases persons who supplied the drink were morally guilty of manslaughter." One of the jury said that hundreds of men could "sup" eight or nine pints and "you could not tell." He stated, too, what may have a germ of truth in it, that half the men take beer to make them sleep. This man's example will not, it is to be feared, do much good, for he said, "I was thirty years drinking and do not think I was two years sober. I am living now, and am turned sixty." The love of drinking for its own sake is still prevalent enough among British workmen. The poor wretch who was killed left a wife and eight children—as Mr. Smelt said—to starve.

Ladies and the Children's Hospital.

At the annual meeting of the subscribers to the Ladies' Fund connected with the Children's Hospital at Pendlebury, an interesting account was given of its origin. A public meeting was held in April, 1893, to consider the financial condition of the hospital, for it was causing much anxiety. A ladies' council was formed as the outcome of this meeting, and immediate steps were taken to organise a systematic canvass of the suburbs of the city. At the first meeting of this council, a year ago, it was reported that £1400 had been collected, and, after deducting expenses, £1375 was handed over to the treasurer. It was felt that it would be a cause for deep regret if the interest caused by these special efforts were not sustained, and it was determined to carry on the work. At the meeting the other day it was announced that £1271 had been received, of which £1257 had been paid to the hospital. A network of branches has been permanently established, and twelve of the districts have subscribed the necessary £50 to obtain cots bearing their respective names. Some of the other charities in Manchester might follow this example with advantage.

April 3rd.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

At the annual meeting of this institution, of which a notice appeared in THE LANCET of March 30th, the President, Mr. Wm. Kendrick, M.P., alluded to the difficulty in keeping up the necessary subscriptions to maintain so large a building. He suggested that the burden might be relieved if people would endow memorial beds therein to the memory of their deceased friends. Such a memorial would certainly be as appropriate as the placing of a window in a church, and would be of great value to the institution. This is a very practical way of looking at the subject, but it seems that the illustration is hardly to be viewed under the same conditions. It was noted in the report of the Jaffray suburban branch attached to the General Hospital that Miss Elizabeth Reay, of Handsworth, had bequeathed the sum of £2500, free of legacy duty, for the endowment of two beds; it was stated that already there were seven endowed beds in the hospital.

The Medical Institute.

The annual meeting was held on March 28th, under the presidency of Dr. W. E. Parkes. The report, in mentioning the fact that it was now twenty years since the institute was founded, congratulated the members that after

many difficulties, financial and otherwise, there was now no debt. An excellent library of 11,000 odd volumes, an income considerably more than half of the annual expenditure derived from investment, and a roll of 175 members, gave ground for confidence and trust in the future. Still, it was a matter for regret that with so large a medical population in the district only a comparatively small proportion were members of this valuable institute. Now that the position is assured and the advantages of membership so obvious, it is to be hoped that a larger number will recognise their duty as well as their privilege in joining it.

The Skin and Lock Hospital.

The fourteenth annual meeting of this charity was held on the 26th ult. The Rev. W. H. Poulton presided. The committee invited attention to the extraordinary development of the institution: 167 in-patients were admitted during the year, and 5421 out-patients, being an increase of 577. The financial condition was not so satisfactory, there being a decrease of £57 in the income, while the expenditure increased £61. Additional accommodation was urgently needed, but in the face of diminished income it was thought unwise to recommend it for the present. Various votes of thanks were passed.

Window-cleaning Accidents.

An inquest was held on March 26th on the body of a man aged fifty-six years, who fell from a window at the Queen's Hospital. In standing on the outside sill the deceased fell into the street and sustained fatal injuries. The coroner, Mr. Oliver Pemberton, called attention to the provisions of the Consolidation Act against standing upon the outside sill to clean windows. A verdict of "Accidental death" was returned. In former years there was need of some law upon this subject, but it is pointed out by a correspondent in the local press that a simple and inexpensive method can be provided whereby both sides of the window can be cleaned from inside the room. By means of this the risk and danger may be avoided.

Workhouse Diet.

It appears from the report that the diet of the inmates of the workhouse has been revised and made more liberal. In future instead of 1½ oz. of tea to a gallon of water 1½ oz. will be allowed, and the 4 oz. of sugar increased to 5 oz. Various other additions were made, but the *crux* of the discussion arose upon the amount of suet necessary to make a pudding; formerly 1 oz. was used to 15 oz. of flour, in future 2 oz. is to be allowed, though sundry members of the board thought this insufficient. Bread and cheese were mentioned as alternatives, and some time was spent in talking of the advantages of a fish diet. On the whole the paupers have occasion to be satisfied with the attention and care given to their condition and comforts.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis in Cattle.

ON Saturday last an interesting and instructive lecture was given by the Heath Professor of Comparative Pathology at a meeting of the Farmers' Club, Newcastle-upon-Tyne. Mr. W. A. Watson Armstrong presided. During the lecture Professor Murray said that when an animal was found to be suffering from tuberculosis it should be fattened for the butcher and the meat sold. He should like it to be sold, however, with a special mark upon it so that those who bought it should know it was from a tuberculous animal. This plan was in vogue in Germany. Danger only arose if the meat was eaten without being thoroughly cooked. These observations are of considerable importance. At present in this country it is a serious offence against the law to offer for sale the flesh of a tuberculous animal, and there are constant convictions in the police-courts and heavy fines imposed by the magistrates upon those who infringe the law by offering for sale tuberculous carcasses. In these hard times it seems wrong that food fit for human consumption under certain precautions in cooking should be destroyed. If Professor Murray's contention be correct, it would seem that some alteration in the law is desirable, so that tuberculous meat may in this country be utilised as it is elsewhere. At any rate, the matter is

worthy of careful consideration by those who are responsible for the making of our laws.

Death of Mr. J. Sang.

On Friday last this well-known and universally respected member of the medical profession died at his residence, Newcastle-upon-Tyne. Mr. Sang qualified in the year 1827, and during his long career in Newcastle was connected with many benevolent institutions. To within a very short time previous to his death, though blind, he was able to get about a little accompanied by his daughter, who devoted her life to taking care of her father.

The Heath and Stephen Scott Scholarships at the University of Durham College of Medicine.

In accordance with the will of the late Dr. G. Y. Heath, Professor of Surgery in the University of Durham, and President of the University of Durham College of Medicine, the trustees of the Heath Scholarship, Professor W. C. Arnison and Mr. Frederick Page, will award and pay to the writer of the best essay on Surgical Diseases of the Jaws the sum of £200. All graduates in medicine or in surgery of the University of Durham are eligible to compete for this prize. The essay must be type-written or printed, and delivered to the trustees not later than March 31st, 1896. The essay, together with any specimens, drawings, casts, microscopical preparations, or other means of illustration accompanying it, will become the property of the College of Medicine, Newcastle-upon-Tyne, but by permission the essay may be printed for general circulation by the Heath Scholar. Mr. Stephen Scott of Harrogate has generously presented to the College of Medicine the sum of £1000, which has been devoted, in accordance with Mr. Scott's wish, to founding a scholarship to promote the study of hernia and allied subjects. Any graduate in medicine or surgery of the University of Durham, or any student of the University of Durham College of Medicine, is eligible to compete for the scholarship, provided that such student shall have had at least one academical year in attendance at the College, and that in any case his age does not exceed thirty years at the time when the essay is sent in. The competition takes place every year. Essays for this year's competition must be sent not later than July 31st, 1895, to Professor Arnison, University of Durham College of Medicine, Newcastle-upon-Tyne.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Judicial Decision under the Edinburgh Dairy Regulations.

AN important case, arising out of the Edinburgh new regulations for dairies, was tried in the Sheriff Court this week. The Lord Provost, magistrates, and town council of Edinburgh, as local authority under the Public Health (Scotland) Act, were the complainers, and the action was against a Mrs. Thomson, a general provision dealer and dairywoman. She was charged with having contravened one of the regulations made by them by selling ham, cheese, groceries, firewood, and other articles in her dairy premises, and of having continued to do so notwithstanding that she had received notice that she was acting in contravention of the regulations. The main objection to this charge was that the regulation relied upon was *ultra vires* of the local authority. The sheriff pointed out, in giving his judgment, that the regulations referred to had been framed by the local authority in 1893, "under and by virtue of the powers vested in them by the Order of Privy Council of 1885 and the Amending Order by the Local Government Board of 1887." Among the regulations is the following: "No purveyor of milk, or person selling by retail, shall carry on within his registered premises any business which, in the opinion of the local authority, is of such a nature that its continuance shall tend to contaminate the milk." The sheriff considered he could not pronounce a judgment against the defender unless it was perfectly clear that the prosecutor had a lawful warrant for asking him to do so. He held that the regulation, for the breaking of which the action was raised, was *ultra vires* of the local authority. The power given by the Privy Council Order was, *inter alia*, "for prescribing precautions to be taken by purveyors of milk by retail against infection or contamination," but the regulation

in question went far beyond this. It was not properly a regulation prescribing any precaution to be adopted by persons selling milk by retail, but it was an absolute prohibition against such persons carrying on any trade or business which in the opinion of the local authority was of such a nature that its continuance would tend to contaminate the milk. If the words "in the opinion of the local authority" had not been inserted, there might have been something to say for it; but then the complaint would have had to be framed differently, and the complainers would have been obliged to set forth not only the nature of the business carried on by the respondent, but also that it was one conducive to the contamination of milk with whatever precautions it might be conducted, and they would have had to prove that, had it been disputed. It seemed to the sheriff that a conviction could not competently follow upon the complaint, and he did not find any sanction for the penalty attached by the complainers. The respondent was allowed five guineas of modified expenses.

Female Medical Students at the University Examinations in Edinburgh.

For the first time in the history of the Edinburgh University a number of female students have appeared for the first professional examination in medicine, which is at present being held. Nearly all the candidates are from the College for Women in Chambers-street, which is under the wing of the Scottish Association for the Medical Education of Women, and most of them have been successful in passing.

The Edinburgh Royal Infirmary.

The friends of the Royal Infirmary are rejoicing over the legacy of £50,000 left to it by the Earl of Moray, and those interested are speculating as to the effect it may have in determining the managers to proceed with the proposed extensions. At the meeting of managers on Monday the new presidents who were appointed were given copies of fresh regulations bearing upon their conduct in the residency. This has unfortunately been brought about from the somewhat boisterous nature of some of the entertainments during the winter.

Edinburgh Royal Maternity Hospital.

At the annual meeting in connexion with this hospital it was intimated that there was a credit balance on the year of £327. The number of inside patients had been 310 and outside patients 610, making 80 more than during the previous year.

The University of St. Andrews.

At a largely attended meeting of the general council of St. Andrews University, held last week under the presidency of the Marquis of Bute, a motion was adopted by 74 votes to 38 approving of the action of the University Court in deciding to found from the Berry Bequest two additional medical chairs at St. Andrews.

The Glasgow Eastern Medical Society.

The committee on organisation of this society having published certain recommendations to the members to guide them in their dealings with public bodies, I give them without comment, as, firstly, their tenour is very clear, and, secondly, they are only recommendations, not having yet been adopted by the society. (1) If the Procurator-Fiscal asks any member for information none should be given unless requested in writing, fee for which to be one guinea; (2) the doctor who first saw deceased ought to be joined with the official post-mortem examiner at the post mortem, fee for which to be one guinea; (3) all service at street accidents, whether the member is called in by citizen or policeman, ought to be paid for by the Commissioners; (4) the English and Irish parochial surgeons are dismissable by the Local Government Board only—it is desirable that the Scottish surgeons be put upon the same footing; (5) it is desirable, in cases of lunacy, that the patient's medical adviser sign one of the certificates, and be paid for it by the parochial board; (6) all certificates of death being public documents should be paid for by the Registrar-General—the certificate should be sent direct by the practitioner, and secrecy be maintained in regard to it by the Registrar; (7) certificates asked for by the School Board should be paid for by that Board; (8) an official should be appointed to investigate the condition of all applying for dispensary treatment, and no free medicine be given; (9) our society should fix the minimum fee per member per annum at five shillings, and juvenile societies should be at the same rate or higher; and (10) the society should use all its influence in

endeavouring to throw open the election of all the members of the General Medical Council to all registered practitioners.

A Complimentary Dinner to Dr. J. F. Sutherland.

On Tuesday, March 26th, the Glasgow Caithness Benevolent Association entertained Dr. J. Francis Sutherland at a complimentary dinner on the occasion of his having been appointed Visiting Commissioner in Lunacy for Scotland. In the course of his reply to the toast of "The Guest of the Evening," which was proposed by Baillie W. Primrose, Dr. Sutherland spoke of the certainty that the country was on the eve of legislation in regard to the habitual drunkard, and compared, in apparent unconsciousness of the double *entente* of his words, the labours of the Scottish Committee, who had examined one hundred and fifty witnesses for a population of four millions, with those of the English Committee on the same subject, who examined but twenty-two witnesses for a population of thirty millions.

Measles Epidemic in Aberdeen: Zymotic Diseases.

Measles began to assume an epidemic form in October last, when there were 73 cases of sickness and 1 death. In November there were 251 new cases and 5 deaths. In December the fresh cases numbered 1102, and there were 39 deaths; in January 1008 additional cases were reported and 47 deaths; in February there were 720 new patients and 43 deaths. The epidemic is now on the decline, the number of cases for the week ended March 9th being 153, in the next week 135, in the week ended March 23rd 112. The following is the return of the cases notified to the medical officer of health for the week ending Saturday, March 30th: Measles, 87; scarlet fever, 6; diphtheria, 1; whooping-cough, 8; erysipelas, 2: total cases 105, being 32 fewer than in the preceding week.

Aberdeen University: Honorary Degrees.

The Senatus has conferred the degree of LL.D. on Sir John Russell Reynolds, Bart., M.D., F.R.S., President of the Royal College of Physicians of London; Surgeon-Colonel Robert Harvey, M.D., F.R.C.P., D.S.O., who presided over the recent Indian Medical Congress; and Sir William McGregor, M.D., K.C.M.G., Administrator of British New Guinea. Of these the last two are distinguished alumni of Aberdeen University. The list of honorary degrees this year is also remarkable from the fact that for the first time in the history of Scottish universities a lady is among the recipients. The lady is Miss Jane E. Harrison, the well-known writer on Greek art and mythology.

New Convalescent Hospital for Aberdeen.

The directors of the Royal Infirmary have been inquiring as to the site for a new convalescent hospital to take the place of the one at Loch-head, which is situated in the city itself and has been sold to the directors of the Royal Lunatic Asylum. It is proposed to build the new hospital in the country. The committee found it impracticable to get a supply of water for one location looked at and have been necessitated to advertise for a building site at some little distance from the city and near to a railway station—"a good supply of water, with ample sewage outlet, essential." Such a site for such a purpose will not easily be got.

Public Nursing Classes in Aberdeen.

Over 200 ladies have attended the public nursing classes in Aberdeen conducted by Dr. J. Scott Riddell. After defraying all expenses the class has been able to hand over to the Ambulance Association about £7. Mrs. Ogston presented the medals and certificates in the large hall of the Young Men's Christian Association to the successful candidates and was accorded a vote of thanks. Professor Alexander Ogston acknowledged the compliment paid to his wife in suitable and humorous terms.

April 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

THE regulations for the Fellowship examination in this College have recently been revised, improved, and altered in many particulars. A resolution has also been passed by the Council by which the Court of Examiners will for the future be consolidated. The two examiners in each subject will thus examine candidates for the Fellowship, Dental, and other diplomas as well as for the Licence of the College.

No less than eighty candidates presented themselves for the preliminary examination last week.

A Groundless Charge against a Poor-law Medical Officer.

A special meeting of the Cashel Dispensary committee was held at John-street, Cashel, on Thursday, the 28th ult., for the purpose of taking into consideration a communication from the Local Government Board in reference to the discharge of the duties of the medical officer of the district. During the investigation it transpired that the action of the Board was caused by a letter addressed to it by a man named Timothy Ryan, in which Mr. Cusacks was accused of neglect of duty. This man subsequently wrote to the dispensary committee (a communication which was read) stating that he had never perused the letter to the Local Government Board. Mr. Cusack, in reply to the communication from the Local Government Board, denied the allegation and invited the fullest inquiry into his action as medical officer. Many members of the committee expressed their full confidence in Mr. Cusack, while a strong letter to the same effect was read from the Very Rev. the Dean of Cashel, who was unavoidably absent. Ultimately the following resolution was passed unanimously.

"The committee of management have had before them Dr. Cusack's letter with enclosures, and while they do not object to any such inquiry as he desires, they feel he would be justified in treating the communication sent to the Local Government Board under the circumstances stated in Timothy Ryan's letter to the committee to-day with contempt. The committee, as well as the poor of the district, know too well how satisfactorily and courteously Dr. Cusack has always discharged his duties. The committee most willingly bear testimony to the great care he has always bestowed on the sick poor, and for this very reason they deeply regret he should be subject to any annoyance in the discharge of his duties, and if this annoyance emanates from another union official, as is suggested, the Local Government Board should put a stop to it without delay."

It is satisfactory to note the unanimity and effectiveness of the action taken by this dispensary committee in loyally supporting their medical officer in repelling a false and groundless accusation.

Private Hospitals in Dublin.

The case known in the daily journals as "The Hospital Injunction Case" has not yet been decided. The delay is unfortunate, but from the recent observation of the Vice-Chancellor it seems to be unavoidable. The case stands briefly thus: A house has been taken in Fitzwilliam-square by a lady who wishes to use it as a private or "home" hospital. Many of the residents in the locality, which includes some of the best private houses in the city, object on the plea that the grounds of the square, which is a small one, may be used by convalescent patients, and that the quiet of that somewhat aristocratic quarter may be disturbed by, for instance, the nocturnal screams of patients. A determined effort is now being made to restrain the proprietor of the house by injunction from utilising it for the above-mentioned purpose, and the leaders of the Irish Bar have had their say on both sides of the question. The judgment of the Vice-Chancellor is now awaited with interest, for his decision will probably affect the position of many other private hospitals and "homes," the multiplication of which in Dublin has been one of the most striking of the local medical developments of the last few years.

Mater Misericordiae Hospital.

Mr. Coppinger's case of innominate aneurysm, of which a brief notice was published on the 23rd ult., continues to do well, both wounds having healed "per primam."

New Medical Magistrates.

Mr. McNulty, L.R.C.P. and S. Edin., Skreen, has been appointed to the Commission of the Peace for the county of Sligo; Mr. Shanahan, L.R.C.S. Irel., Kilmacthomas, to the Commission of the Peace for the county of Waterford; and Mr. J. F. Roden, L.R.C.P. and S. Edin., Headen, to the Commission of the Peace for the county of Limerick.

Sir David Barbour at Queen's College, Belfast.

On Monday, April 1st, at a meeting of the Queen's College Literary and Scientific Society, Sir David Barbour, K.C.S.I., an old *alumnus* of Queen's College, Belfast, who has recently returned from India after having attained the high position of Finance Minister, delivered an address on Bimetallism. Sir David Barbour thinks that the experience of the last twenty-two years appears to afford an irresistible argument in favour of using both gold and silver as the future standard of value. The question to be considered was not whether we shall use gold alone as the world's standard of value, but what is the best method by which gold and silver can both be maintained

as standard money. Sir David Barbour, who was a guest of the President of Queen's College during his stay in Belfast, has left to lecture in Dublin.

The New Asylum at Purdysburn.

A meeting of the farmers and residents in the neighbourhood of Purdysburn was held on April 1st to protest against the proposal of the Belfast Asylum authorities to run the sewage of the new asylum at Purdysburn into the Purdysburn river. It seems that, owing to the peculiar nature of the soil of the district and the almost total absence of springs, the people have depended on the river for their supply of water at all seasons of the year. It was stated that more than 500 families use the river. A deputation was appointed to lay the views of those present at the meeting before the asylum authorities.

Death of Dr. Daniel Jamison.

The very greatest regret was felt in medical and other circles on March 31st when it was announced that one of the younger members of the profession, Dr. Daniel Jamison, had succumbed to an attack of typhus fever. There has been an outbreak of the disease in the Falls district of Belfast, said to have been introduced into the city by a girl from Lisburn. Dr. Jamison, in the course of his duty as dispensary officer, was called to attend several of the patients, and in this way he contracted the disease which has been so fatal to medical men in all parts of Ireland. Dr. Jamison graduated in 1890, and a few years ago was appointed a dispensary officer. He was greatly respected for his many good qualities and his death is deeply deplored.

The Witchcraft Case at Clonmel.

The witchcraft horror still absorbs a considerable amount of public attention, and the ghastly details brought out in evidence clearly indicate that the unfortunate husband had lived on terms of affection with his wife. He firmly believed she had been spirited away and a supernatural being substituted in her place. Fully impressed with the idea that the only way in which he could recover his wife was by ejecting the supposed witch, he acquiesced in the ordeal by fire, and with the assistance of the unfortunate woman's father and other near relatives, inflicted the terrible injuries already detailed. Public indignation runs so high in the neighbourhood that the authorities find it prudent to surround the prisoners by a very strong guard of constabulary as they are marched from the Bidawell to the court, and the groaning of the crowd is principally directed against the "herb doctor." The latter moves in a very humble sphere of life, and his healing powers have been "inherited" from his father and grandfather!

The Bishop of Cork.

I have definitely learned that the Right Reverend Dr. Meade and his coachman have arrived in Paris, and so far are progressing very well under the care of Professor Pasteur. The spinal cord of the dog has been submitted to Professor Pasteur with a view to a positive diagnosis being made as to whether the animal suffered from rabies. Doubt has been expressed upon this point, but several cases of that disease have recently occurred in this district, and only a few weeks ago a child was bitten by a rabid dog at Douglas, a village two miles from Cork. The Poor-law guardians, with commendable promptness, proposed to send the little sufferer in charge of the relieving officer to Paris, but the parents refused to allow the child to go unless they could accompany it, and the guardians could not see their way to incurring the additional expenditure.

Cork Lunatic Asylum.

At the last meeting of the board of governors of this institution the medical superintendent reported that recently a patient had a struggle with some of the attendants and on examination afterwards it was found that three of his ribs were broken. The board decided that a searching investigation should be held for the purpose of ascertaining whether any unnecessary violence had been used.

Died at the Post of Duty.

Sister Evelyn (Miss Adams), Cork, who recently completed her period of probation at the South Infirmary and afterwards joined the staff of the North Fever Hospital to acquire a knowledge of fever nursing, contracted typhus fever whilst in the latter institution. The medical and nursing staffs were unremitting in their care of her, but her health had been previously somewhat run down, and the disease assumed a virulent type which medical skill and kindly nursing failed to combat.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Astigmatism or Astigmia?

In the current number of the *Annales d'Oculistique* Dr. Georges Martin of Bordeaux publishes a suggestive article on the correct nomenclature of the above condition. He reminds us that Dr. Whewell, when he invented the word astigmatism, meant to describe a condition in which rays emitted by a luminous point and traversing an eye of which the cornea or the lens are refracted less in the vertical axis than in the other axis, and could not consequently be brought to a focus or point on the retina. But Dr. Martin contends that Whewell should have chosen for his purpose, not *στιγμα*, *στιγματος* (which really means *puncture*), but *στιγμή*, *στιγμής* which signifies a mathematical point. He points out that the word *stigmata* is commonly employed to describe the wounds made in Our Saviour's feet and hands by the nails of the Cross. Before, however, bringing the new word *astigmie* to the notice of the profession, Dr. Martin consulted two competent Hellenists—M. Oavré, Professor of the Faculty of Letters of Bordeaux, and M. Monnier, Law Professor at the same Faculty and a well-known Greek scholar. Dr. Martin adduces, as a further reason for the adoption of the new term *astigmie* (*astigmia*), the fact that the innovation would justify the use of the current word *astigmatometer*, which should logically be written *astigmatometer* under the old nomenclature. My friend Dr. Bull of Paris, to whom I am indebted for this information, tells me that Dr. Martin's view has met with such acceptance that he himself (Dr. Bull) and Dr. Javal and Dr. Parent intend to employ the word *astigmia* to the exclusion of Whewell's term *astigmatism*, and that the official sanction of the next Ophthalmological Congress will be sought for the innovation.

The Medical and Cognate Professions in Alsace-Lorraine.

All information relating to the former French provinces, Alsace-Lorraine, is naturally eagerly welcomed by our Gallic neighbours, and my *confrères* in England will perhaps be interested in the census of the medical, pharmaceutical, and dental population of the latest recruit (excepting Heligoland) to the German Empire. The number of medical practitioners in Alsace-Lorraine is 653, 149 of these being army medical men. Of the pharmacists, whose number is strictly limited by law, there exist 333. The dental profession will grieve when they hear that their comrades in the whole of Alsace-Lorraine only number 12. Of the 504 civil medical men, 83 possess French diplomas (Alsace 60 and Lorraine 23), being a diminution of 7 on the figures of last year. There still survive in the two provinces 3 *officiers de santé*. Of 333 pharmacists, 16 only hold French diplomas, whereas 21 out of 67 veterinary surgeons were educated at French schools. The fathers of the medical profession in Alsace-Lorraine are Dr. Berdotz, sen., of Colmar and Dr. Scheidecker of Rothau, who qualified in 1829 and 1831 respectively.

Ocular Chancre.

A lecture on the above-mentioned rare affection was recently delivered at St. Louis by Professor Fournier. In 1850 Ricord gave a complete description of this phenomenon, and Zeiss later counted one ocular chancre in 20,000. If we may rely on recent statistics furnished by Fortinades, the proportion has increased forty times (1 in 500). The lesion may occupy one of three situations—whole palpebral (rare), ciliary and invading also either the cutaneous or the mucous aspects of the lid (the most common), or exclusively conjunctival (the rarest). Chancres involving the internal angle are at least twice as common as those situated at the external canthus. The lesion is almost invariably single and generally no other chancre exists on the body. Nevertheless, such coincidences do occasionally occur, and a patient now in Professor Fournier's wards has two chancres—one at the external angle of the eye and another on the chin. More commonly met with in the man than in the woman, it is seen at all ages, which circumstance is in favour of its accidental, non-venereal origin in a good many instances. In a large proportion of cases the etiology is problematical; in other words, the cause is an accidental one. The cause will, however, come under one of the three following heads: (1) direct contagion, (2) contamination through the fingers, and (3) mediate contagion. In direct contagion kissing occupies the chief place. Then, again, infected saliva may accidentally be projected on to the eyelid, as in the inspection of the fauces of a syphilitic

subject by a medical man. Professor Fournier has come across five fellow-practitioners who became syphilitic in this way. Three of them assured him that they had immediately washed their faces thoroughly. In such a predicament the prompt application of an antiseptic such as corrosive sublimate solution is necessary. Again, a bite or suction has sufficed for infection. One example given is that of a boxer who went home with an extensive ecchymosis of the lower lid. A woman who had buccal mucous patches pricked the swollen lid and sucked the wound in order to evacuate the effused blood. A chancre was the result. The tongue may convey the virus, as in the practice followed in certain countries for the extraction of foreign bodies of the eyelid. A Russian confrère, Dr. Teplyaschin, relates how an epidemic of syphilis reigned in a small village, the source of the mischief being a "wise woman" renowned for this kind of practice. Infants have been infected through the saliva of a syphilitic nurse or mother, it being the custom in some countries to wash the child's eyes with the spittle. The chancre of the palpebral border presents itself under the aspect of a tumour of the eyelid as large as a haricot bean or the half of an olive. It is a hard erosive neoplasm. The surface is generally smooth and red; sometimes it is, however, covered with a brown or yellowish crust. The only part of the chancre that is eroded is the conjunctival surface. The chancre of the external angle is fissured, being composed of two portions separated by a rhagade. The glands affected in chancres of the inner angle are submaxillary, in those of the outer angle preauricular and parotidian, although a chain extending from the preauricular gland to the clavicle may be noticed in certain cases.

A New Obstetrical Department.

The new Maternity forming part of the Beaujon Hospital is at last completed. It contains fifty-eight beds, forty being reserved for women actually in labour, twelve for pregnant women, and six for purposes of isolation. The sum of 75,161 francs has just been voted by the municipal council for the furnishing of these wards. The accoucheur of the Beaujon Maternity is Dr. Ribemont-Dessaignes, to whom is due the credit of having done away with the old microbe-laden obstetrical wards in favour of the modern premises.

The Congress at Bordeaux.

The Secretary-General of the Congress to be held under the auspices of the Société de Gynécologie, d'Obstétrique, et de Pédiatrie de Bordeaux in that city in August communicates the three subjects to which special attention will be directed: (1) Gynecology—Uterine Displacements; (2) Obstetrics—Treatment of Puerperal Septicæmia; (3) Pediatrics—Malformation of Lower Limb, Subluxation of Hip, and Clubfoot.

April 2nd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A New Epidemic in Berlin.

APHTHOUS fever, an affection identical with bovine foot-and-mouth disease, has been for some years constantly present in several places in the neighbourhood of Berlin. This year it has invaded the city, and, although for the present only a part of Berlin is infected, the epidemic will undoubtedly spread over the whole town if no preventive measures are taken. An excellent description of its pathology has been given by Dr. Siegel in the *Deutsche Medicinische Wochenschrift* of 1891, the year in which the disease first appeared. Dr. Siegel is a practitioner in Britz, a village near Berlin, where many cattle are kept by the inhabitants. He is of opinion that in the human subject incubation lasts eight or ten days; the patients are then seized with shivering, giddiness, and an inclination to vomit. Most of them become hoarse; the skin assumes a yellowish-grey colour, and, as a rule, there is obstinate constipation. The temperature is usually not very high; in Dr. Siegel's cases it never rose above 39.5° C. This stage of the illness lasts from three to eight days; then swelling of the tongue and gums, loosening of the teeth, and intense fœtor of the breath ensue; at the same time little blisters appear on the tongue, the lips, and the skin of the legs. The blisters in the mouth very soon break and form small ulcers, those on the legs are often so close-set that they resemble the eruption of measles. All these symptoms disappear after a

few days, and the patients enter on the convalescent stage. The disease, however, is not always of so mild a character, and in some cases there have been very alarming complications. In one case shown to the Surgical Association the swelling of the tongue was so intense that it was tightly compressed by the teeth and became partly gangrenous. Another very grave symptom was bleeding from the gums, the tongue, and the stomach. Sometimes the eruption on the legs resembled pemphigus and formed large ulcers which were somewhat slow of healing. Orchitis was found in some cases, whilst albuminuria was very uncommon. Notwithstanding these grave complications, the death-rate of the disease was low; Dr. Siegel had only six deaths in 400 cases. In a second communication to the *Deutsche Medicinische Wochenschrift* of 1894 Dr. Siegel completed his description. In addition to the regions already mentioned, he has observed the blisters on the mammae of nursing women, the prepuce, and the conjunctiva. He distinguishes three forms of the disease—viz., intestinal, pectoral, and cutaneous, according to the predominance of the symptoms in the respective organs. He has had good therapeutic results with salicylate of potassium. The cause of the disease is, in his opinion, a bacillus which he has found post mortem in the liver and kidneys. This bacillus is somewhat short, being only 0.5-0.7 μ in length; its ends are rounded and are more intensely dyed by aniline colours than the middle portion; it has no mobility and can be cultivated on gelatine without liquefying it; it also thrives on agar, blood-serum, and potatoes; it cannot be stained by Gram's method. At a recent meeting of the Medical Society Dr. Siegel, who has made apthous fever his speciality, stated that in some cases this year there were no blisters at all during the course of the illness, the principal symptoms being only obstinate constipation and general malaise. The bacillus which he had formerly found only in the organs post mortem has now been seen by him also in the excreta. He has succeeded in producing typical foot-and-mouth disease in cattle by inoculating cultures of the bacillus. Although there is no doubt that the disease is transmitted by milk he had never found these bacilli in it, and it would seem that they are destroyed by the numerous other bacteria which the milk contains. He says that the only way to prevent the propagation of the disease is to kill all the cattle affected with foot-and-mouth disease; for this purpose a very strict control would have to be exercised over all the cowhouses of the infected places. As the disease is of very great interest the Medical Society will soon discuss the matter, and if the number of patients increases perhaps a collective investigation will be undertaken. The members have already been asked to send notes of their cases to the secretary of the society.

The Helmholtz Monument.

A monument will be erected in Berlin in honour of the late Professor Helmholtz. For this purpose a committee has been formed under the presidency of Dr. Delbrück, former Secretary of State, and a friend of the deceased *savant*. The medical members of the committee are Professor Dubois-Reymond, the celebrated physiologist, Professor Fränkel, Professor Liebreich, and Professor Virchow. Professor König, the successor of Helmholtz in his chair at the University of Berlin, will act as honorary secretary. The Emperor has contributed £500, and other subscriptions to a considerable amount have been received.

Influenza in Berlin.

Influenza, which has been endemic here for the last five years and became prevalent nearly every winter, has this year attacked an uncommonly large number of people. Persons whose business keeps them a great deal of the day at home or in offices seem to be more liable to it than those who work out of doors. Many serious inconveniences have been caused by the epidemic; in the law courts, the Government offices, and other establishments business was often stopped because the officials and employés were for the most part ill. The exact number of the sick cannot be given as the official health statistics only report the number of deaths. In the week from Feb. 12th to 18th influenza caused only 5 deaths; Feb. 19th to 25th, 21 deaths; Feb. 26th to March 2nd, 67 deaths; and March 3rd to 9th, 95 deaths. There were also a great many fatal cases of pneumonia associated with influenza. In the last-mentioned week the epidemic seemed to have reached its acme and has since declined. The complications were both numerous and grave. In addition to affections of the

respiratory organs suppurations have been observed in the bones, joints, ears, and other parts of the body. There has been no discussion as yet in the medical societies, and it is therefore impossible to give further particulars at present.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Death of Professor Rinaldo Roseo.

WE have just lost our very able and popular Professor of Medical Jurisprudence. Professor Rinaldo Roseo had been for some time labouring under a vesical affection which ultimately required an operation. He repaired for that purpose to the Clinica Chirurgica directed by his friend and colleague, Professor Durante, in whose skilful hands all went well for some days, till suddenly and unexpectedly a rigor declared itself as the prelude to severe convulsive attacks, which carried him off on the 25th inst. Professor Roseo was not more than forty-eight years of age, but he had early in life established a solid reputation for acquisitive and original power. Legal medicine in all its ramifications was his special department, and on the chair reserved for it in the Sapienza becoming vacant he offered himself as a candidate. The election was by comparative trial, and a number of formidable competitors presented themselves. He distanced them all, however, and the examiners gave public expression to their gratification at having secured for the University so able and accomplished a teacher in a subject so important. Indefatigable in the laboratory and most painstaking in his prælections, he was one of the most attractive occupants of a university chair in Italy. In the law courts he commanded respect and even deference by his tact and conciliatory power in making scientific evidence prevail over legal technicality and routine precedent. He even mingled, on occasions of political crisis, in the public questions of the day, and contested, happily without success, the first and then the fourth electoral division of Rome. I say happily, for, as all his friends perceived, his devotion to duty was such that, had he been returned to Parliament, he would have given his constituents an amount of his time and thought that he could not, compatibly with health, have spared from his academic and forensic avocations. He did good service as Assessore dell'Igiene—a post for which his great knowledge of State medicine and his interest in the sanitary welfare of the community eminently fitted him. His funeral was attended by all the Senatus Academicus and students of the University, by the Grand Orient of Freemasons, in which he held high office, by the chief representatives of the great public bodies, communal and municipal, and by the delegates of the leading literary and scientific societies.

Enrico Canori.

Another academic loss is that of Enrico Canori, one of the most brilliant students of medicine in the Roman school. He was just on the eve of graduation, and would have more than justified the expectations of his teachers and class fellows when he succumbed to pyæmia. It will be long before the Sapienza boasts of another prosector and assistant teacher of equal promise.

March 31st.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

The Club Question.

I HAVE received the following circular, which speaks for itself:—

"The present very inadequate scale of remuneration made by the majority of sick clubs to their doctor was originally accepted by the latter in consequence of such societies having been regarded as charitable institutions (especially established for unskilled working men and their families), the members of which appealed to the philanthropy of the profession for services to which the pay bore no relation to the value of their skill, time, and labour. The present enlarged means of the members of sick clubs generally (among whom are not only skilled artisans, whose earnings are now greater than in former years, but tradesmen and others whose position in life renders them able to pay the customary medical fees, and whose self-respect should induce them to bear in mind the rule of 'live and let live') should, therefore, not merely as a matter of justice, but of policy, incite them to remunerate their medical officers on a scale more proportional to the value of their services than the existing one, and one better calculated to promote the mutual confidence and respect which should

subsist between members and their doctors; for although inadequate payment affords no justification for the omission of duty on the part of the latter, still the probability, nay, the moral certainty, cannot be ignored that a fair and liberal remuneration would, by insuring increased medical attention, tend (humanly speaking) to shorten the duration of disease, and thus, to no inconsiderable extent, lessen the demand upon the several club funds for 'sick pay.' Moreover, it is of importance, as affecting the financial position of clubs, that every member should on admission be in sound health and free from any hereditary or marked tendency to disease. This can only be ascertained by a careful medical examination—a work of time and skill; and it is but reasonable that a moderate fee should be paid for the trouble and responsibility incurred."

The very hard work which the club medical officer has to undertake, especially during epidemics and in scattered localities, is indeed not adequately met by this existing scale of remuneration. The wages of workmen in this colony are on a high scale, and skilled labour is handsomely rewarded. When it is taken into consideration, on the one hand, that to obtain a satisfactory medical qualification nowadays real hard work is absolutely essential, and that it entails the expenditure of extended time and much money, and, on the other, that the wage of workmen is so high, surely members of clubs and friendly societies ought to be able to recompense professional attention in a more satisfactory manner as far as their medical officer is concerned. Personally I have no interest in clubs or friendly societies, but I see quite enough in my own district to be entirely convinced that persons with thousands of pounds at their command are mean enough to secure medical attention at an absurd rate under cover of being members of this or that club or friendly society. Why should a man with, say, a thousand a year, meeting with an accident, such as a fractured thigh, or being the victim of typhoid fever, receive all the skilled attention necessary to meet his case for the paltry pittance which the friendly societies offer? The whole matter rests with the members of the profession themselves, and I hope that the time is shortly coming when the subject of clubs &c. will be placed on a more satisfactory basis so far as the hardworking medical man is concerned.

The Wright Fund.

This fund, raised by subscription among the members of the medical profession in New Zealand, amounts as the mail leaves to £184 odd. The almost unanimous response which was made to the suggestion that aid should be given to Dr. Wright as a small token of sympathy is very satisfactory to the chief promoters of the scheme, and especially so to the recipient, who in the latest issue of the *New Zealand Medical Journal* cordially thanks the members of his profession for their sympathy, which has been exhibited in such a practical manner.

Wanganui, Feb. 23th.

Obituary.

JAMES HENRY COVENEY, M.R.C.S. ENG., L.S.A.

WE regret to announce the death, on the 26th ult., of Mr. James H. Coveney, who for many years was engaged in private practice at Prestwich, near Manchester. Mr. Coveney was the son of the late Captain James Coveney of the 60th Rifles, and was born at Stilton, Hunts. He was educated at the Huntingdon Grammar School and St. Bartholomew's Hospital, and subsequently, after obtaining the diplomas of the Royal College of Surgeons of England and the Society of Apothecaries, he held the office of Physician's Assistant at the Royal Infirmary, Manchester, later becoming attached to the Royal School of Medicine at Manchester as Lecturer on Surgery. While engaged in practice in Prestwich Mr. Coveney held the appointments of district medical officer and of medical officer of health. He retired in 1886, to the great regret of his patients, who had been accustomed to rely on his skill and kindness during the many years he had lived among them. On his retirement he was presented by those who had learnt to value his services and his friendship with a handsome token of their esteem. His remaining years he passed at Hawkhurst, in Kent.

EDMUND GRUNDY, M.R.C.S. ENG., L.S.A.

MANY old friends and patients will feel more than a passing regret at the announcement of the death of Mr. Grundy of Bury, Lancashire, who succumbed to an attack of bronchitis

on March 20th, at the great age of eighty-seven years. He was the son of Mr. Edmund Grundy, the first Parliamentary representative of Bury after it became a borough. Having obtained his medical education in Dublin, he passed the examination of the Society of Apothecaries in 1829, and became a member of the Royal College of Surgeons of England in the following year. He then commenced practice in Bury, and from that time onward, as long as health and strength permitted, he continued in the active exercise of his profession in Bury or the vicinity. Mr. Grundy was a widower, and leaves one son.

JOHN GROVE, M.D. ST. AND., M.R.C.S. ENG., L.S.A.

DR. GROVE, whose death has been already announced in our columns, was within a month of attaining his eightieth year when he passed away on March 6th at his residence in Gloucester, where he had for some years made his home. He was born in Bethnal-green and was of French extraction, a circumstance to which he probably owed in some degree the enthusiasm of his character. He commenced medical practice in Wandsworth in 1840, having in that year qualified as M.R.C.S. and L.S.A., and from that time till 1860 led the busy life of an active general practitioner and medical officer to the board of guardians. He was a zealous investigator of clinical problems, and indefatigable in searching for the remote causes which underlie and lead up to the phenomena of disease. During the cholera epidemic of 1848-49 he placed great reliance on the use of sulphur both internally and externally, and published his views in a pamphlet which was reviewed in our columns on Oct. 20th, 1849. In the same number of THE LANCET appeared the first of three articles by him entitled "The Vitality of the Choleraic Fungi Demonstrated," in which he argued on behalf of the specific character of mycelium growths observed in the urine of cholera patients. Although subsequent investigations have not supported his conclusions as to the particular organism the general idea was sound, and the view that disease might originate in a living growth was then comparatively new. Dr. Richardson in 1877 and Mr. Dolan in 1881 bore witness to the originality of his work, the latter speaking of him as "the first in modern times to advocate the hypothesis that living germs are the exciting agents of epidemic and infectious disease." Dr. Grove also wrote on the microscopical character of lymph and the method and results of inoculation. Other works of his were "Epidemics examined and explained, or Living Germs proved by Analogy to be a Source of Disease," "Aphtha, and its Important Relations as an Epidemic Disease," and "Contagion and Infection in relation to Epidemic Diseases," this last being a reprint from the *Journal of Medical Science* for November, 1853. Dr. Grove's last contribution to the literature of his special subject was "The Unity of the Laws which govern the Exciting Agents of Epidemic, Endemic, and Infectious Diseases," on which he wrote in the *Transactions of the Epidemiological Society* for 1851 and the *Medical Press* of January, 1852. About 1852 Dr. Grove became a Fellow of the Royal Medical and Chirurgical Society, and in 1852 he graduated as M.D. at the University of St. Andrews.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF PRESIDENT.

At a special meeting of the Council of the College held at the College on Thursday, April 4th, Mr. Reginald Harrison, the Senior Vice-President, in the chair, Mr. Christopher Heath was elected President of the College in the room of Mr. John Whitaker Hulke, F.R.S., deceased, for the remainder of the collegiate year. Mr. Heath's election will therefore run until Thursday, July 11th, 1895, the second Thursday in the month.

The choice of the Council had been very generally anticipated.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen have passed the Second Examination of the Board in the subjects indicated:—

Monday, April 1st:—

Anatomy and Physiology.—Isaac Taylor, student of Yorkshire College, Leeds; Roland Wilfred Pearson, Henry Harold Robinson, James Bennett, and James Wood, Owens College, Manchester; Joseph Black, Owens College, Manchester, and Firth College, Sheffield; John Gardner and Norton Milner, Firth College, Sheffield; Frank Barnes, Frank Newstead Deakin, Wilfred Henry Coltart, John Godfrey Crosswell Taunton, John Bradley, Francis Pope, and John Augustus Noel Longley, Mason College, Birmingham; Arthur Wren Tuxford, St. Mary's Hospital; Walter Rodney Battye, University Colleges, Bristol and London; and John Worthington Hughes, Cambridge University.

Anatomy only.—Messrs. Henry Spinks, James Wallwork, and Herbert Blakemore, Owens College, Manchester; Frederick Charles Morgan and Charles Martin Mitchell, University College, Bristol.

Physiology only.—Messrs. Graham Renshaw and Herbert Lancaster Lordman, Owens College, Manchester; and Owen Treadwell Athley Phillips, University College, Cardiff.

Twelve gentlemen were referred in both subjects, four in anatomy only, and five in physiology only.

Tuesday, April 2nd:—

Anatomy and Physiology.—William Edmund Jones, student of Owens College, Manchester; William Edward Bee Roberts, Mason College, Birmingham; Edward Charles Sawley and Edward Septimus Graham, St. Mary's Hospital; Edwin Vincent Foss and Robert Fletcher Moorshead, University College, Bristol; George Llewellyn Bates and Walter John May, Charing-cross Hospital; Robert Wynne Charles Pierce, William Hancock Tucker, and Harry Edward Hewitt, St. Thomas's Hospital; George Conyns Marrack, St. Bartholomew's Hospital; Harold John Ercart, Westminster Hospital; Lionel Edwin Charles Handson, Guy's Hospital; Thomas Jones, London Hospital; Alphonse Roman, Tubingen, Strassburg, and Kiel Universities; Herbert Alexander Bruce, Toronto University and University College, London.

Anatomy only.—Edward Smyth Crispin, King's College, London; Joseph Lewin Payne, Guy's Hospital; Alfred John Andrew, St. Bartholomew's Hospital; Polham Christopher Maitland, Middlesex Hospital; and John Edward Hocking Parsons, Cambridge University and Guy's Hospital.

Physiology only.—James Michael Aloysius Manning, St. George's Hospital; Donald Ackland, Charing-cross Hospital; and Austin Ronald O'Flahertie, London Hospital and Mr. Cooke's School of Anatomy and Physiology.

Ten gentlemen were referred in both subjects, five in anatomy only, and six in physiology only.

THE VICTORIA UNIVERSITY.—The following candidates passed in March, 1895, in the subjects indicated:—

Final M.B. Examination: Part I.—G. F. Bowman, Owens College; Archibald Brushfield, Owens College; H. S. H. Callum, Yorkshire College; C. E. Ligertwood, Yorkshire College; F. C. Moore, Owens College; J. V. Shaw, Yorkshire College; Spencer Thorp, Owens College; R. H. Trotter, Yorkshire College.

Part II.—Hugh Ainsworth, Owens College; C. S. Ashe, Owens College; R. E. Bickerton, University College; D. E. Darbyshire, University College; F. W. Fish, Owens College; J. P. Hall, Owens College; J. J. H. Holt, Owens College; W. A. Newall, Owens College; H. A. Scott, Owens College; W. L. Spink, Yorkshire College; J. S. Taggart, Owens College.

The following have been awarded Honours:—*First Class.*—Hugh Ainsworth, Owens College; J. S. Taggart, Owens College. *Second Class.*—J. P. Hall, Owens College.

Second M.B. Examination: (a) Anatomy and Physiology.—J. T. Auld, Owens College; Mark Augier, University College; T. F. Bamford, Owens College; W. H. Bateman, Owens College; William Bradley, Owens College; J. J. Butterworth, Owens College; H. J. Crompton, Owens College; L. O. Delecourt, Owens College; J. E. Dutton, University College; Walter Graham, University College; A. S. Griffith, University College; Harold Hartley, Owens College; J. F. Hodgson, Owens College; D. G. Hurter, University College; Robert Kelsall, Owens College; James Kemp, Owens College; G. G. L. Lawson, University College; F. T. A. Lovegrove, University College; J. H. Mason, Yorkshire College; H. A. Mawdsley, University College; W. T. Mellington, Owens College; John Milne, Owens College; H. G. H. Monk, Yorkshire College; John Mooney, Owens College; C. H. Moorhouse, Yorkshire College; John Prestwich, Owens College; A. H. Priestley, Owens College; Graham Renshaw, Owens College; J. H. Sheldon, Owens College; Robert Sutherland, University College; Harold Thorp, Owens College; L. S. Whitman, University College; J. H. Willett, University College; Joshua Williamson, Yorkshire College; D. S. Wylie, Owens College.

(b) Materia Medica and Pharmacy.—D. A. Ashton, Owens College; J. T. Auld, Owens College; T. F. Bamford, Owens College; R. W. Bollans, Yorkshire College; H. N. Bridge, Owens College; Lucy Buckley, University College; W. J. S. Bythell, Owens College; H. R. Clarke, Owens College; Francis Darlow, Yorkshire College; J. W. Dearden, Yorkshire College; Walter Graham, University College; Roland Hamer, Owens College; T. W. Hart, Owens College; Harold Hartley, Owens College; Walter Hickey, Owens College; D. G. Hurter, University College; Robert Kelsall, Owens College; G. G. L. Lawson, University College; E. J. Martin, Owens College; Thomas O'Neill, Owens College; A. H. Priestley, Owens College; C. R. Schofield, Owens College; J. H. Sheldon, Owens

College: Harry Slater, Owens College; Robert Sutherland, University College; H. de P. B. Veale, Yorkshire College; J. V. Watson, Owens College; William Wright, Owens College.
The Scholarship in Medicine is awarded to Robert Kelsall, Owens College.

UNIVERSITY OF ST. ANDREWS.—The following registered medical practitioners, having passed the required examinations, received the degree of Doctor of Medicine on March 29th, 1895:—

George Henry Darwin, F.R.C.P. Edin., L.F.P.S. Glasg., Didsbury.
Samuel Barjona Fairley, L.S.A. Lond., L.F.P.S. Glasg., Aston.
John Joyner Fraser, L.R.C.P. Edin., F.R.C.S. Edin., Hesse.
James Robert Haynes, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A. Lond., London.
Lewis Leon James, L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S. Glasg., Edinburgh.
John Dysart McCaw, F.R.C.S. Edin., L.R.C.P. Edin., L.S.A. Lond., London.
James Bruce Ronaldson, L.R.C.P. Edin., F.R.C.S. Edin., L.A.H. Dublin, D.P.H., Haddington.
St. Clair Brokway Shadwell, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H., Walthamstow.
Thomas Willey, M.R.C.S. Eng., L.R.C.P. Lond., Tunbridge Wells.
Isaac Williams, L.R.C.S. Edin., L.M. Edin., London.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—A festival dinner in aid of the funds of this hospital was held on April 2nd in the Whitehall Rooms, Hôtel Métropole. H.R.H. the Duke of Cambridge presided, and among the company were Lord Halsbury, Field-Marshal Sir Donald Stewart, General Sir Redvers Buller, the President of the Royal College of Physicians of London (Sir J. Russell Reynolds), Sir J. Crichton Browne, and Dr. Gowers. The chairman stated that the Queen had contributed £50 to the funds of the charity, and he expressed a confident hope that its finances would be maintained in a satisfactory position by the generosity of the public. In response to the toast of his own health the Duke expressed his deep interest in all the charitable institutions of this country, and strongly deprecated any innovation which was likely to change their character of voluntarily supported charities. The toast of "The Medical and Surgical Staff of the Hospital" was proposed by the President of the Royal College of Physicians of London, and Dr. Gowers, in his reply, emphasised the importance of the position which the hospital was assuming, as the centre of neurological teaching in this country. Subscriptions to the amount of £4440 were announced by the secretary.

THE LEEDS GENERAL INFIRMARY.—We have received the annual report of the Leeds General Infirmary for the year 1894, which appeared last month, being its 127th yearly issue. The total number of beds in constant use was 394, of which 90 per cent. were continuously in occupation. The number of in-patients admitted was 5714, which with 295 remaining at the end of 1893 makes a total of 6009 treated during the year. The average daily number of beds occupied was 353, and the average length of residence of each patient was twenty-two days. The rate of mortality was 6.14 per cent., but, deducting the large number of patients (107) who died within forty-eight hours after admission, the percentage is reduced to 4.44. Of the deaths, 31 were due to burns and scalds, chiefly in young children; 91 were the result of accidents; and 116 inquests were held. The total number of out-patients treated, including 192 in the electrical department, was 40,827. Of those who applied as out-patients about 150 were rejected as being in a position to pay for treatment. In the maternity department there were 706 confinements. The Ida Hospital of forty-two beds serves to relieve the pressure on the wards of the infirmary; there were 696 patients transferred to it, and of them 2 died. During the year the horse ambulance has been used 518 times. On many occasions it was sent for persons who were found to be quite able to walk, and in 44 instances when it reached the place to which it was summoned there was no patient to be brought. The average cost of each in-patient for treatment, nursing, and maintenance was at the rate of 17s. 11½d. per week; or, inclusive of outlay on fittings, furniture, and repairs to buildings, 21s. 3½d. per week. The total income was £22,070, and the total expenditure on the infirmary and the Ida Hospital was £24,202. At the end of the year the serious debt of £6021 remained. In conclusion, the weekly board express their profound regret at the death of Dr. E. H. Jacob, who had for many years been connected with the infirmary, first as resident medical officer, then as assistant physician, and for the past three years as physician.

THE usual quarterly meeting of the General Council of the Royal British Nurses' Association will be held at 17, Old Cavendish-street, on Friday, April 19th, 1895, at 5 P.M.

THE CHARGE AGAINST A MIDWIFE.—Mildred Mary Rake, the certified midwife who has been standing her trial for manslaughter, the charge being that she had caused the death of one of her patients by communicating to her puerperal fever, was released on Tuesday on bail, the jury having been unable to agree on a verdict.

NOTTINGHAM SAMARITAN HOSPITAL.—The annual meeting of this hospital was held on March 27th at the Exchange Hall, Nottingham, the Mayor presiding. Dr. Elder presented the medical report, which showed that during 1894 there were 171 in-patients admitted, and that 148 operations were performed, including 18 cases of ovariectomy, all of which were successful, 35 abdominal sections for diseases of the uterine appendages, in 2 cases ending fatally, and 5 abdominal sections for the treatment of uterine myomata. During the year there were 4 deaths, one of the cases being a patient who was not operated on, and died from heart disease. The total income amounted to £704, and the expenditure to £884; a sum of £946 is owing to the bankers, and strenuous efforts are being made to obtain increased subscriptions.

PLYMOUTH MEDICAL SOCIETY.—A clinical evening was held on Wednesday, March 27th, Dr. Lawrence Fox in the chair.—Mr. Whiteford related the case of a man aged fifty who fourteen years ago fell and injured the left shoulder; seven years later an abscess pointed and was opened just below the clavicle. Six years ago a sinus formed on the anterior axillary fold and at intervals has discharged synovia. About 15° of movement are now possible, and members were asked as to their views of treatment of the case. Mr. Woolcombe exhibited for Mr. Swain a mass of black human hair weighing 5lb. 3oz. removed by the latter on March 20th from the stomach of an unmarried girl aged twenty by median abdominal section and gastrotomy. The patient is doing well, the sutures having been removed eight days after operation. A full account of this case will be published later by Mr. Swain.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—The forty-sixth annual meeting of the governors of the Wolverhampton and Staffordshire General Hospital was held at the Bell Medical Library on March 12th. The report for the year 1894 stated that the number of in-patients treated during the past year has been 2100; of these 873 were medical and 1227 were surgical cases; 1357 as accidents, or urgent cases, were admitted without tickets. The number of attendances of out-patients during the year has been 47,695, showing an average of 917 per week. The number of in-patients in the preceding year was 14,918. The ordinary income for the past year has amounted to £7375 0s. 9d., being a decrease of £171 17s. 2d. as compared with the previous year. A new mortuary with rooms attached, for pathological and microscopic work, was commenced and finished at a cost of £800.

THE ROYAL EYE HOSPITAL, SOUTHWARK.—On March 27th the annual general meeting of the governors of this institution was held at the hospital in a ward which is unfortunately closed for want of funds. Professor McHardy, one of the surgeons, occupied the chair. The report for 1894 showed that during the year there were 13,337 new cases, of which 490 were in-patients, and that £2488 in Consols had been sold to supplement the still inadequate annual income of the charity. Mr. Henry Irving was unanimously elected a vice-president, and it was announced that Mr. R. K. Causton, M.P., would preside at the festival banquet on June 18th next. It is confidently hoped that as the public become acquainted with the work of this ophthalmic hospital they will assist it with such supplementary income as may be needful to fully utilise its advantages in the service of the sight-endangered poor of South London. The chairman mentioned that the Royal Ophthalmic Hospital at Moorfields, following the example of this hospital, is abandoning its present obsolete premises and erecting new buildings upon a more economical and suitable site. Various eminent architects and ophthalmic surgeons who have visited the hospital at Southwark had, he stated, greatly admired its general design and its adaptation to the purposes which it is intended to serve.

THE ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS, E.C.—The annual meeting of this charity was held at the hospital on March 28th, Mr. C. Gordon presiding. The report showed that 1881 in-patients were treated during the past year, and that there were 24,500 out-patients, who made 113,000 attendances. In 1863 cases spectacles were either provided gratuitously or assistance was given towards the purchase of them. The total income for the year was £7620, and the ordinary expenditure was £6883. There was, however, an extraordinary expenditure of £4080, made up of a sum of £2850, the cost of a site for a new hospital, together with a large outlay in connexion with an abortive scheme for enlarging the existing hospital. The site of the present building would be sold, a plot of land having been acquired on a 999 years' lease in the City-road for the erection of new premises, which were expected to be ready in about two years.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Shop Hours Question.

SIR JOHN LUBBOCK'S Committee on the Shops' Early Closing Bill have now before them a considerable body of opinion against the fixing of a legal limit. Representatives of the Voluntary Early Closing Association were examined this week, who claimed that there is still a large field for successful voluntary effort. One of these representatives, Mr. Bryce Grant, explained that he had written to the medical men connected with the association on the subject of the hours worked in shops in London, and had got from seven of them replies to the effect that they could not attribute suffering and illness to these hours.

Habitual Offenders and Inebriates.

The Committee, of which Sir Charles Cameron is chairman, appointed to inquire into the treatment of habitual offenders and inebriates, has completed its inquiry so far as the taking of evidence is concerned, and is now busy with the preparation of its report.

HOUSE OF COMMONS.

THURSDAY, MARCH 28TH.

The Government Veterinary Department.

Mr. Herbert Gardner, replying to a question on this subject, said that on the retirement of the late director of the Veterinary Department in December, 1893, he found it necessary to redistribute the business performed by the principal officers so as to enable the scientific officers to devote themselves exclusively to work for which the possession of veterinary knowledge was requisite, and to place the business of an executive and non-professional character in the hands of the officers best qualified to perform it. The new organisation had been in full operation for the past fifteen months, and there was no vacant post to be filled, nor was it necessary to make any new professional appointment now that the scientific officers were in a position to devote themselves to professional work.

The Meat-supply for the Army.

Mr. W. Field questioned the Secretary of State for War with reference to the proposed tenders for meat-supplies to the troops stationed at Dublin for the six months commencing June 1st next.—Mr. Campbell-Bannerman, in his reply, said that the tenders for meat for the Dublin garrison, like those for other stations, would be for both fresh and refrigerated meat. The conditions prescribed did not amount to a preference for foreign meat, but they admitted it into restricted competition with home supplies. This was not a departure from the general system, but an application of the general system to the Dublin garrison. Several military abattoirs were established many years ago, chiefly to secure the efficiency of butchers for field service and for the instruction of officers in connexion with meat-supplies. These purposes had been attained, and a sufficient supply of military butchers could be kept efficient with a smaller number of abattoirs, while the instruction of officers in judging meat is specially provided for. Abattoirs were expensive, and the contract system had recently been reverted to at Portsmouth with satisfactory results. The same course was proposed for Dublin, where the decision had been hastened by the fact that if the abattoir had been retained a large expenditure would have been necessary for its reconstruction. In reply to further questions on this subject, Mr. Campbell-Bannerman said that the question of the allowance of meat was very elaborately inquired into three or four years ago, and he thought they had better leave it where it stood.

FRIDAY, MARCH 29TH.

The Indian Civil Service.

Mr. Herbert Gladstone, replying on behalf of Mr. Henry Fowler to a question on this subject, said that the Government of India had submitted proposals respecting the leave rules of the various civil departments in India. These were now under the consideration of the Secretary of State, but before a final decision could be passed on all points a further reference to the Government of India would probably be necessary.

Flogging in the Indian Army.

On the motion for the third reading of the Army (Annual) Bill, Mr. Hanbury made reference to the continuance of the provision for flogging natives in the Indian army. This form of punishment, he

pointed out, had been abolished in the case of white men, and he thought it a most invidious thing to have the two classes of men working together as they did in India and elsewhere, with one liable to flogging and the other free from it. He thought the distinction should be at once abolished.

MONDAY, APRIL 1ST.

The North-Eastern Fever Hospital.

Mr. Bartley asked the President of the Local Government Board whether his attention had been called to the alleged cases of the consequences of the too early discharge of patients from the North-Eastern Fever Hospital; whether he had seen the letter of Feb. 11th from the Islington medical officer of health on the subject, addressed to the Local Government Board, but not yet replied to; whether he was aware that, in the case of Mr. Holland's children, two died and the father was attacked with scarlet fever, having caught the fever, it was alleged, from the third child, who was sent home while still desquamating; and whether he would order an inquiry into the whole matter?—Mr. Shaw-Lefevre replied that he had communicated with the manager of the Metropolitan Asylums District, who had caused full inquiry to be made into the case of Mr. Holland and the children. There appeared to be no justification for attributing the disease of the father and children to any infection arising from the premature discharge of the child from the hospital. The clerk stated that in the case of the two children there was strict evidence that the disease was diphtheria and not scarlet fever.

The Explosion at Fenchurch-street Station.

In reply to a question on this subject, Mr. Asquith said he was advised that scientific opinion differed as to whether the bursting of the cylinder was due to the pressure of oxygen upon an imperfectly-welded steel tube or to traces of impure substances present in the oxygen. He proposed to refer the question for the opinion of two or three distinguished experts.

The Importation of Margarine.

The Chancellor of the Exchequer, replying to a question by Mr. Lambert, said the Board of Customs were advised that the Margarine Act of 1897 imposed no duty on their officers with regard to importations of margarine marked with a detachable tin or parchment label to designate the contents. Their powers were limited to the taking of samples under Section 8 of the Act.

The Government and Irish Lunatic Asylums.

Mr. John Morley stated, in answer to a question, that a suggestion had been made to him with respect to an increase of the Government capitation grant for lunatic asylum boards in Ireland. The Government grant was first made in 1874 and was fixed at 4s. per week in respect of each patient. The average cost of maintenance was £24 1s. 2d. in the year 1875, as against £21 14s. in 1893 (the last year for which this information was available), so that no increase had taken place in those years in the cost of maintenance. The capitation grant was made with a view to the improved maintenance and treatment of the insane poor, and was not applicable to meet the cost of structural alterations of asylums, for which separate loans were granted under an Act of 1893.

In-door Paupers in London.

In reply to a series of questions by London members, Mr. Shaw Lefevre, President of the Local Government Board, said that under Section 43 of the Local Government Act of 1883 the amount of the grant of 4d. per day for each in-door pauper paid to each metropolitan union by the London County Council was determined by the average number of in-door paupers maintained in the union during the five financial years ended on March 25th, 1888, and the section expressly declared that it should continue to be reckoned in accordance with the same average number unless Parliament otherwise determined. If, therefore, the basis of the apportionment of this grant was to be altered, legislation would be necessary, and he should not be justified in submitting any proposals to Parliament on the matter until he had had full opportunity of ascertaining the views held with respect to it by the London County Council, who had to pay the grant, and the various boards of guardians who received it.

WEDNESDAY, APRIL 3RD.

The Care of Steam Engines.

A long discussion took place on the motion for the second reading of a Bill which provides for the examination and certification of persons in charge of steam engines. In order to increase its prospect of being carried, the promoters agreed to withdraw from the scope of the Bill persons in charge of steam engines engaged in agriculture, railways, and shipping. Some members objected to the usefulness of the Bill being thus curtailed, and Mr. John Burns pleaded that at least steam tugs, river boats, and small steam fishing vessels should be included, on the ground that in these craft accidents were frequent. The Bill in its limited form was, however, read a second time, and it was decided to refer it to the consideration of a select committee. Several of the speakers in the course of the debate cited cases where serious accidents had occurred through engines being left in the care of incompetent workmen.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on this subject resumed its inquiry on Tuesday, April 2nd, with Sir Walter Foster in the chair.

Mr. W. L. Stokes of Limerick, who represented the South of Ireland Butter Merchants' Association, said in the course of examination by the chairman that the attention of the butter trade in Ireland had been very specially directed to the question of water in butter by certain prosecutions instituted in England for supposed excessive moisture in Irish butter. These prosecutions were a revelation to the people engaged in the Irish butter trade, who in consequence took steps to have the butter examined in order that it might not lose in reputation. The opinion they came to was that the butter could be brought down to the standard set up by the analysts, and the view of his association was that by going round to the different bodies and getting inspectors appointed they would be able to get the butter down to that

standard. In the course of 1893 and 1894 they took 350 samples indiscriminately in all the markets and sent them for analysis, and they found that the moisture in them varied from 8 to 30 per cent. He attributed excess of moisture in Irish butter partly to temperature and partly to defective appliances. They had also carried on experiments with regard to the preserving of butter, and had obtained better results from using warm brine and salt than from using a preservative like boracic acid. For Irish salt butter there was a great demand in England because of its quality and its keeping capacity. He had known it keep for five or six months. He strongly objected to any legal standard of moisture. If an analyst knew his business he should be able to distinguish between honestly made butter and butter with water added for the purpose of fraud. In his opinion there had been great and general improvement in Irish butter during the last ten years, owing, he believed, to better education among farmers and to the stimulus of competition in the butter trade.

By Mr. Kilbride. While he was opposed to a legal standard of moisture being fixed, he thought 18 or 20 per cent. might prove a reasonable standard for normal seasons. During such a season as 1893, with its high temperature, it would have been utterly impossible to insist upon a standard. He was opposed to butter mixtures and the colouring of margarine, because in his view they conduced to fraud.

Mr. Robert Gibson, another representative of the South of Ireland Butter Merchants' Association, expressed the opinion that it was impossible to fix a standard for moisture which would not interfere with an honest man honestly doing his best in certain circumstances. He cited to the Committee a number of cases where high percentages of water were found in butter made with the most modern machinery by acknowledged experts. Asked how he would protect the public from excess of moisture, witness said he did not believe the public were prejudiced, because they were very good judges of butter and were quick to detect the presence of water.

Mr. Robert Hickey, secretary of the association, gave the results of analyses of butter churned and made in various conditions. These went to show that butter made in the same dairy and during the same week might vary with regard to the moisture it contained to the extent of 8 and 9 per cent. His fear was that the fixing of a standard of moisture would lead not to levelling up, but to levelling down, and that water would be introduced into butter which now contained only a very slight percentage of it. In the case of Irish salt butter it would be most injuriously affected by a standard, because it was absolutely necessary for keeping purposes to use a considerable amount of brine. A standard of 16 per cent. of moisture would affect injuriously five-sixths of the butter made in the province of Munster. The association had passed a number of resolutions, in which they disclaimed any desire to interfere with the legitimate sale of margarine, but said that the colouring of margarine to imitate butter should be prohibited; that all margarine should be sold in specially shaped packages so that the purchaser might know what he was getting; and that the mixing of margarine and butter should be prohibited. It was a matter of common knowledge that a large trade was done between Limerick and Rotterdam and some Austrian ports in empty Irish firkins, and the only conclusion they could come to, although they had no positive proof, was that these empty firkins were imported for the purpose of being filled with margarine.

The Committee then adjourned.

The Committee met again on Wednesday, April 3rd, Sir Walter Foster presiding.

Mr. C. J. Dunne, chairman of the Cork Butter Market Trustees, said that, in his opinion, the present law with regard to the adulteration of butter did not afford sufficient protection either to the public or to the honest manufacturer. Fraud was so profitable that fines of £2, £5, or £10 had no effect, and his view was that the maximum fine should be as high as £500. He favoured a high fine rather than imprisonment, because the men who adulterated butter did so for the sake of the profit they made. They were told, though he could not produce direct evidence on the point, that people who sold margarine mixtures promised the retailers that if they were convicted the fines would be paid for them. If fines of £500 were imposed these promises would not be made. The Market Trustees had passed a resolution condemning the practice of colouring margarine so as to simulate butter. In his opinion the Local Government Board in Ireland, and in England also, should have power to compel local authorities to put the law as to adulteration into operation, just as they compelled boards of guardians to carry out the Poor-law. He suggested further, that all dealers in margarine should be licensed, and should be compelled to let their customers know that they were licensed. The question of water in butter was a most difficult one, and the conclusion he had come to was that at the present moment there had not been sufficient investigation with regard to it to justify the fixing of a legal standard. If, as had been suggested, a standard of 16 per cent. of moisture were adopted, it might in certain circumstances cause quite innocent persons to be punished. In the Cork market they had a simple apparatus for testing the moisture, and whenever their inspectors had any suspicion of an undue amount of moisture they sent up the butter to the room where this apparatus was kept, and the test did not occupy more than ten minutes. The results of this test corresponded to within one-half per cent. with the results obtained from chemical analysis. If less than 18 per cent. of moisture were found in butter, it was passed. If there were between 18 and 21 per cent. they did not consider it a case for prosecution, but at the same time they did not consider the butter good enough to get any of the brands of the market. The committee might take it that when they found more than 21 per cent. of moisture, there was a prosecution. He had with him a series of figures showing that in forty-one cases where there had been convictions the percentage of water had varied from 21.26 to 27.24. A sub-committee of the Munster Dairy and Agricultural School were at present engaged upon a most careful inquiry into this and cognate matters. They had got about 200 samples of butter, mostly made by small farmers in the county of Cork, twenty samples from Sweden, and six from Australia. Among other points being considered by them was the comparative keeping properties of butter mixed with dry salt and with warm brine. He could not agree with Mr. Gibson that the public were quick to detect the presence of an excessive amount of moisture in butter. On the contrary he thought they were easily deceived and that deception and fraud were common.

Alderman Henry Dale, representing the Cork Butter Exporters' Association, stated that he preserved his butter with dry salt and used no brine whatever. He considered salt to be as good a preservative as brine, and it had the advantage that it had not the tendency to add water to the butter that brine had. He put in several reports of analysis of samples of butter in county Cork with the view of showing the great range of variation which the samples exhibited in the percentage of water. In the case of one maker the lowest percentage of water found in his butter was 13.4 and the highest 17.65; while in the case of another maker the results came out 12.67 and 20.30 respectively. The result of the tests and analysis was to establish the fact that more water was found in the butter in the month of October than at any other period of the year. He believed that experienced inspectors could tell pretty accurately whether the water in butter was there naturally or added to it with fraudulent intent. He had no objection to margarine as an article of food, but thought it should be sold in special packages and cases. Increased and more effective inspection would favour the large producer so far as high-class butter was concerned, as the competition with margarine would be diminished. He suggested the putting of starch in margarine as a means for its easier identification and preventing its being fraudulently substituted for butter.

Mr. William O'Sullivan, another trader from Cork, gave evidence of a corroborative character.

Mr. Thomas Clement, of the firm of Andrew Clement and Son, provision merchants and colonial produce importers, Glasgow, Manchester, and London, stated that, while, owing to the increased importation of cheap butter, margarine mixtures were much less sold, the trade in margarine itself was a rapidly increasing one. It was greatly used by people who could not afford to pay for butter, and for cooking purposes and for baking and confectionery. There was much less inducement now than formerly to sell margarine as butter, because the retailer could make almost as much profit upon the one commodity as the other, and in the case of margarine there was the risk of prosecution and exposure. He regarded margarine as a necessary article of food, and beyond requiring that it should be made in a certain shape and bear a special mark he would put no restriction upon its honest sale. He would make the invoice a legal guarantee and prosecute the wholesale merchant who sold the adulterated butter, instead of being content with the retailer. In his experience he found that an enormous quantity of what was called pure butter was imported into this country which contained 15 and 20 per cent. of margarine and 20 to 25 per cent. of water, and to prevent fraud in this connexion he would have strict inspection at the port of entry and call upon the local authorities to do their duty. There was also a great quantity of adulterated cheese imported. In regard to cream and milk witness said that large quantities were imported from abroad without any guarantee whatsoever that they were free from the germs of disease. He was aware that in forty-eight towns in England, with an aggregate population of one and a half millions, not one sample of butter was taken by the local authorities during the year 1893, and he thought it most desirable to stir the local authorities in some way to a proper sense of duty.

The Committee then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

- ANHWORTH, J. HENRY, M.D. St. And., F.F.P.S. Glasg., M.R.C.P. Edin., has been appointed Medical Officer to the Post Office, Halesd, Essex.
- ASTIN, WILSON, M.B., C.M. Aberd., has been appointed Assistant Medical Officer to "Oriolet" Cottage Hospital for Cancer, Loughton, Essex.
- BARNETT, H. C., L.R.C.P., C.M. Edin., L.R.C.S. Eng., has been re-appointed Medical Superintendent to the Fremantle Lunatic Asylum, Western Australia.
- BARNITT, L. E., M.B., Ch.M. Edin., L.R.C.P. Lond., F.R.C.S., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.
- BELSON, GEO. DE V., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Dulverton Union.
- BIRD, RICH'D. K., L.R.C.P., L.M., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Health Officer for Arapiles Shire, N.R., Victoria, Australia.
- BOWSER, H. C., M.R.C.S. Eng., L.M. Edin., has been appointed Resident Surgeon to the Gladstone Hospital, Queensland.
- BROOKS, CHAS., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Chalfont Sanitary District of the Amersham Union.
- BURGHARD, FRÉDÉRIC F., M.S. Lond., F.R.C.S., has been appointed Surgeon to Out-patients at the Paddington-green Children's Hospital.
- CLARK, ANDREW, F.R.C.S., L.M., has been appointed Surgeon to the Middlesex Hospital, vice J. W. Hulke deceased.
- CLOSS, J. O., M.B., Ch.M. Edin., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.
- COLQUHOUN, D., M.D. Lond., M.R.C.P., M.R.C.S., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.
- CROSSLEY, A. W., Ph.D. Würzburg, M.Sc. Victoria, Berkeley Fellow and Demonstrator of Organic Chemistry in the Owens College, Manchester, has been appointed Demonstrator of Chemistry in the Medical School of St. Thomas's Hospital, vice W. H. Ince.
- CURRY, E. F. N., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Physician to the West London Hospital.
- DAVIES, J. M. L., L.R.C.P., L.M. Edin., M.R.C.S. Eng., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.
- DERMER, WM. T., M.B. Univ. N. Z., has been appointed a Public Vaccinator for the district of Wairoa, New Zealand.
- DICKSON, J. D., M.D., M.Ch., L.R.C.S. Irel., has been appointed Medical Officer of Health for the Wycombe Sanitary District.

DOBBS, JAMES, L.R.C.P., L.R.C.S., has been appointed Medical Officer of Health for the Urban District of Golborne.

ELLIS, J. C., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer and Public Vaccinator for the Fifth District of the Lincoln Union.

FERGUSON, H. L., L.K.Q.C.P., F.R.C.S. Irel., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.

GIBBES, JOHN M., M.D., Ch.M. Aberd., M.R.C.S. Eng., has been appointed a Public Vaccinator for Borderton, South Australia.

GILL, J. M., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Honorary Assistant Physician to the Sydney Hospital, New South Wales.

GILLET, GEO. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Loddon and Clavering Union.

HALAHAN, SAM H., M.B., Ch.B., Dubl., has been appointed Health Officer for Kowree Shire, N.R., Victoria, Australia.

HEARD, CHARLES DE W., M.B. Melb., L.R.C.P., L.R.C.S. Edin., has been appointed Health Officer for Wyndham shire, Victoria, Australia.

HOPKINS, J. W., F.R.C.P. Edin., L.M., L.S.A. Lond., has been appointed Resident Government Medical Officer and Public Vaccinator for the Fremantle district, Western Australia.

HORNE, GEO., M.B., Ch.B. Melb., has been appointed Honorary Medical Officer to the Melbourne Women's Hospital, Victoria, Australia, vice Prendergast, resigned.

HOUGHTON, GEORGE S., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Resident Medical Officer to Montistown Hospital, vice Brew.

JEFFCOAT, F. H., M.B., Ch.M. Edin., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.

LANG, MATTHEW, M.B. Ch.B. Melb., has been appointed a Public Vaccinator at Clunes, Victoria, Australia.

LIMBICK, W. S., L.R.C.P., L.R.C.S. Edin., L.M., has been appointed Medical Officer to the Waterloo Urban District Council.

LINDEN, H. C., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Harptree Sanitary District of the Clutton Union.

LOCK, G. H., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Paddington-green Children's Hospital.

MACALAN, THOMAS, M.B., C.M. Aberd., has been appointed a Public Vaccinator for the Districts of Norsewood and Armondville, New Zealand.

MACDONALD, J., L.R.C.P., L.R.C.S., L.M. Edin., M.R.C.S. Eng., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.

MACKENZIE, MURDOCH, L.R.C.P., L.M., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Health Officer for Poowong and Jeetho Shires, Victoria, Australia.

MACKINNON, JAS., M.B., Ch.M. Edin., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.

MEAKIN, HAROLD B., M.B. Lond., M.R.C.S., L.R.C.P., has been appointed Senior House Physician to the Metropolitan Hospital, Kingsland-road.

RICHARDS, W. H., L.S.A., has been appointed Medical Officer for the St. Mellons Sanitary District of the Newport Union, Mon.

ROBERTS, E. J., M.B., Ch.B. Univ. N.Z., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.

ROPER, ARTHUR C., F.R.C.S., L.R.C.P. Edin., M.R.C.S., has been appointed Surgeon to the Devon and Exeter Hospital, vice J. Baukard, resigned.

ROSEHURST, A. B., M.A., M.B., F.R.C.S., has been appointed Surgical Registrar to the London Hospital, Whitechapel-road.

STENHOUSE, W. MCS., M.D., Ch.M. Glasg., has been appointed Honorary Medical Officer to the Dunedin Hospital, New Zealand.

STRECHES, E. W. LOCKHART, M.R.C.S., has been appointed Medical Officer of Health to the Warlington Urban District.

STEWART, A., M.B., C.M. Glasg., has been appointed surgeon to the Welsh District Hospital, Queensland.

STRUTHERS, JAMES, M.D., Ch.M. Aberd., has been appointed a Medical Officer of the Hospital at Hill End, New South Wales, vice Baker.

TISWELL, FRANK, M.B. Syd., has been appointed Government Bacteriologist, New South Wales.

WALL, M. E., M.D. Munich., has been appointed a Public Vaccinator at Cammockburn, Victoria, Australia.

WALTON, A. P., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for Chiddingfold Sanitary District of Hambledon Union.

WEST, WALDEMAN S., M.A., M.B., B.C. Cantab., has been appointed Obstetric House Physician to the Middlesex Hospital.

WILKINSON, E. W. C., L.F.P.S. Glasg., has been appointed a Public Vaccinator for the District of Foston, New Zealand.

WILSON, GEORGE JOHN, M.A. Oxon, M.D. Dubl., M.R.C.S. Eng., has been appointed Honorary Physician to the Radcliffe Infirmary, Oxford.

WILSON, T. A. M., M.B., M.S. Edin., has been appointed Medical Officer for the Morland Sanitary District of the West Ward Union.

ZICHY-WOJNARSKI, V. J. E., M.B. Melb., has been appointed a Public Vaccinator at West Melbourne, Victoria, Australia.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM CITY ASYLUM.—Resident qualified Clinical Assistant. Board and apartments are provided.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £150 per annum (with an allowance of £30 per annum for cab hire), and furnished rooms, fire, lights, and attendance.

BRITISH LYING-IN HOSPITAL, Endell-street, Longacre, W.C.—Physician to the Out-patient Department.

COUNTY ASYLUM, Dorchester.—Second Assistant Medical Officer, unmarried. Salary to commence at £130, rising £10 annually to £160.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians.

HOSPITAL FOR SICK CHILDREN, THE, Great Ormond-street, W.C.—Anaesthetist, for one year. Honorarium of £15 15s. will be voted at the expiration of that term.

HOSPITAL FOR SICK CHILDREN, THE, Great Ormond-street, W.C.—Surgical Registrar, for one year. Honorarium of £40 at the expiration of that term.

HOSPITAL FOR WOMEN, THE (THE LONDON SCHOOL OF GYNÆCOLOGY), Soho-square, W.—Clinical Assistants.

KENT COUNTY LUNATIC ASYLUM, Barning Heath, near Maidstone.—Fourth Assistant Medical Officer and Pathologist, for two years (unmarried). Salary £175 per annum (rising £5 a year), with furnished quarters, attendance, coal, gas, garden produce, and washing. Applications to Mr. F. R. Howlett, 9, King-street, Maidstone.

LONDON HOSPITAL MEDICAL COLLEGE, THE, Mile End, E.—Assistant Demonstrator of Anatomy. Salary £90 per annum.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Physician. Applications to the Secretary, Office, 27, Clement's-lane, E.C.

NORTHERMBERLAND COUNTY ASYLUM, Morpeth.—Clinical Assistant. Board and residence provided.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Resident Medical Officer and Assistant Resident Medical Officer, for six months. Salary at the rate of £50 per annum attaches to the senior post.

PADDINGTON-GREEN CHILDREN'S HOSPITAL, London, W.—Surgeon for the Throat and Ear Department.

POPULAR HOSPITAL FOR ACCIDENTS, Blackwall, E.—Honorary Surgeon.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon, for six months. Rooms, commons, and washing provided.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, THE, City-road, E.C.—Resident Medical Officer, for six months. Salary at the rate of £100 per annum, with furnished apartments and board.

ROYAL SOUTH HANTS INFIRMARY, Southampton.—Assistant House Surgeon for six months. £10 will be given at the end of that period if found satisfactory. Board and lodging provided.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Examiners.

UNIVERSITY OF GLASGOW.—Two Examiners. The appointment will in each case last till Dec. 31st, 1896, at the rate of £50 annually.

Births, Marriages, and Deaths.

BIRTHS.

GRINDON.—On March 26th, at Olney, Bucks, the wife of F. J. Grindon, M.R.C.S., of a daughter.

HEELIS.—On March 31st, at Church-street, Lenton, Nottingham, the wife of Robert Heelis, M.D., of a daughter.

OPPE.—On March 31st, at Winchester House, Worthing, the wife of Edward A. Oppe, M.B., of a son.

ROUSE.—On March 31st, at Belgrave-road, S.W., the wife of Deputy-Surgeon-General R. Rouse, of a daughter.

WHISHAW.—On March 29th, at Larkstone, Birdhurst-road, Croydon, the wife of Reginald R. Whishaw, M.B., F.R.C.S., of a son.

WIGLESWORTH.—On March 28th, at Hainhill, Lancashire, the wife of Joseph Wiglesworth, M.D., of a son.

MARRIAGES.

BERKELEY—FORDHAM.—On April 3rd, at St. George's, Hanover-square, George Harold Arthur Comyns Berkeley, B.A., M.B., and B.C. Cantab., elder son of George Augustus Berkeley, Esq., of Belgrave-road, S.W., to Ethel Rose, younger daughter of the late Edward King Fordham, Esq., J.P., D.L., of The Bury, Ashwell, Herts.

BROWN—JOHNSTONE.—At the Presbyterian Church, Brompton, on April 1st, by the Rev. Robert Brown, father of the bridegroom, Robert Cunningham Brown, M.B., B.S., to Ella Halliburton, youngest daughter of the late Dr. J. J. Johnstone, of Brampton, Cumberland.

STATION—JENNINGS.—On March 28th, at St. Mark's, Surliton, Henry Foster Staunton, M.B., C.M., M.R.C.S., Green Hammerton, York, to Minnie Isabel, eldest daughter of William Jennings, late of the Mairis Commission, India.

THOMSON—MACKINTOSH.—At St. Giles's Cathedral, Edinburgh, on April 3rd, by the Very Rev. Cameron Lees, D.D., LL.D., Dean of the Chapel Royal and Order of the Thistle, and the Rev. Andrew Gray, D.D., Minister of the Parish of Dalkeith, James Stitt Thomson, F.R.C.P.E., &c., of Belmont, Dalkeith, and The Mount, Lincoln, to Louisa Ella Mary (Edgie), eldest daughter of the late Henry Florence Mackintosh, of Totteridge, Herts, and Rylstone, Yorks.

DEATHS.

ACKLAND.—On March 30th, at St. Luke's-road, Clapham, William Ackland, L.S.A., of the Strand, W.C., aged 74 years.

CLEAVER.—On March 31st, at his residence, Broomhill, Sheffield, William Jackson Cleaver, M.B., aged 47.

CLIPPINGDALE.—On March 29th, at 50, Northfield-road, Stamford Hill, Samuel Dodd Clippingdale, M.R.C.S., in his 85th year.

COVENY.—On March 24th, at The Roost, Hawkhurst, James Henry Coveny, M.R.C.S. Eng.

DUKES.—On April 1st, at South Hackney, William Proft Dukes, L.R.C.P. Edin., M.R.C.S., aged 57 years.

HARVEY.—On March 29th, at Streatham, J. H. Harvey, L.R.C.P. Edin., M.B.C.S., of Prince's-square, Bayswater.

LEPPS.—On March 9th (suddenly), at the Europa Hotel, Gibraltar, Thomas Leeds, M.R.C.S. Eng., M.S.A. Lond., aged 55 years.

THORNTON.—On March 27th, at Marlborough-hill, St. John's-wood, Philip Thornton, M.R.C.S., aged 90.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians. 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Cases:—Dr. G. Johnston: Congenital Chorea.—Dr. Brevor: Facial Hemiatrophy.—Dr. L. Guthrie: (1) Friedreich's Disease; (2) Cerebral Disease.—Mr. S. Edwards: Case after Removal of a Papilloma of the Bladder by Suprapubic Cystotomy.—Mr. Waring: Charcot's Disease.—Mr. Astley Blexam: (1) Restoration of Nose by means of Transplanting portion of the First and the whole of the Second Phalanx of Middle Finger of Left Hand; (2) Macrocheilia.—Mr. Openshaw: Multiple Osteitis.—Mr. Allingham: Large Renal Sarcoma removed from a Child aged three.—Dr. Abraham: (1) Subcutaneous Nodules in an Infant; (2) Devergie's Lichen Pilaris with Psoriasis.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (197, High Holborn).—7.30 P.M. Ordinary Meeting. Election of President. Adjourned Discussion on Mr. Jones's paper on "Drains or Sewers."

TUESDAY.—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—A case of Large Pelvic Hydatid successfully treated by Perineal Incision and Drainage, with Observations by Mr. Reginald Harrison.

WEDNESDAY.—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Mr. E. H. Crisp: Syphilitic Perforation of Septum Nasi.—Mr. A. Knyvett Gordon: Microscopic Sections of (1) Middle Turbinate Body with Polypus Formation and (2) Cured Masses from case of Antral Empyema.—Dr. Dundas Grant: (1) A case of Empyema of the Antrum successfully treated by means of Krause's Trocar; (2) A case of Empyema of the Antrum secondary to Suppuration of the Frontal Sinus successfully treated by means of Krause's Trocar; (3) A case of Empyema of the Antrum under treatment by the same means; (4) A case of Empyema of the Antrum apparently cured by the same means and Closure of the Alveolar Perforation; (5) A case of Empyema of the Antrum complicated with Suppuration of (probably) the Frontal Sinus.—Dr. de Havilland Hall: A case of Mycosis Fungoides involving the Larynx.—Dr. William Hill: A case of Disease of the Left Frontal, Ethmoidal, and Maxillary Sinuses in association with Nasal Polyp. —Dr. J. Middlemass Hunt: A case of Multiple Papillomatosis of Larynx occurring after Removal of Sarcoma by Thyrotomy.—Dr. Percy Kidd: The case of Laryngeal Stenosis with Polypoid Growth of Vocal Cord shown at January meeting, 1895.—Dr. Scanes Spicer: A case of Bilateral Empyema and Polyp of Frontal Sinuses for which Trephining and Curettement have been recently performed, and in which Right Antral Empyema and Polyp have been treated by large Canine Fossa Opening. Inferior Meatus Counter-opening, and Curettement. Ethmoidal Cells partly affected and under treatment.—Mr. Charles J. Symonds: A case of Frontal Sinus Disease under treatment.—Dr. E. B. Waggett: Subglottic Tumour for Diagnosis. Also cases by Mr. A. A. Bowly.

HUNTERIAN SOCIETY.—8 P.M. Dr. Arnold Chaplin: Case for Diagnosis.—Transposition of Viscera.—Dr. Galloway: Cases of Lichen Planus.—Mr. Openshaw: Cases of Cerebral Abscess.

THURSDAY.—BRITISH GYNECOLOGICAL SOCIETY.—Specimens. Adjourned Discussion on Dr. Macnaughton Jones's paper on "The Abuse of Morphia in Gynecology."
DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—5 P.M. Ordinary Meeting. Exhibition of Cases at 4.30 P.M.
NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Great Northern Central Hospital).—9 P.M. Closing Meeting of the Session 1894-95. Address by Dr. J. G. Glover (the President) on "The Profession, its Place and Progress."

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

UNDER no circumstances do the Proprietors authorise the insertion of loose advertisement circulars and handbills in THE LANCET. Any such announcements are inserted by the newsagents, whom the Proprietors cannot control. At the same time, the Manager will be glad if readers will send him copies of any circulars, with the name and address of the agent through whom they obtain THE LANCET, and the Manager will then endeavour to mitigate the nuisance.

"THE CARTOGRAPHY OF MALARIA."

SUPPLEMENTARY to our article on this subject (*vide THE LANCET*, Jan. 5th, 1895) may be read the more extended paper contributed to the March number of the *Scottish Geographical Magazine* by Signor Luigi Bodio, head of the Statistical Department of the Italian Government, under whose superintendence the "Carta della Malaria" was issued. Very interesting are Signor Bodio's remarks on the genesis of malaria in regions where under the Roman Empire it was quite unknown. In those days the Imperial Government maintained a high standard of cultivation throughout the peninsula, drainage being especially well regulated and the rivers canalised and kept navigable. With the irruption of the barbarians, followed by the anarchy, violence, and confusion of the Middle Ages, these works were discontinued; rivers and torrents inundated the fields, obstructing by their own alluvium their discharge into the sea, and thus multiplying the sources of malaria. On this part of the subject Signor Bodio refers the reader to the "Carta della Malaria dell'Italia Illustrata da Luigi Torelli," published in Florence by G. Pellini in 1882—a volume in quarto which should be in the library of every epidemiological society.

Mr F. R. L. Edwards.—Laura Bridgman is the only instance other than in an idiot of loss of sight, hearing, and speech occurring in the same person that has come to our notice. She lost her special senses at the age of two years. Under the treatment of Dr. Howe of Boston she was taught to read, write, and perform most of the ordinary duties of life. She was born in 1829, and we have an idea that she has not long been dead.

Middlesex.—The dose depends upon the preparation. The British Institute of Preventive Medicine (101, Great Russell-street, W.C.) will be able to give all information.

J. R.—A masseur has no special professional status; but we imagine he could claim payment for any services contracted for.

Eucalyptus.—No.

THE CASE OF MR. C. BRYAN TOWNSEND.

THE following donations have been received in addition to those already announced and are hereby thankfully acknowledged:—

Dr. Wm. Henry White ...	£1 1 0	Dr. J. J. Lacey (Fitzington) ...	£3 3 0
B. W. ...	0 10 0	Sir Dyce Duckworth ...	1 1 0
Mr. David Ferrier ...	1 1 0	Dr. Wm. Carter (Liver-	
Mr. A. A. Phillips ...	10 0 0	pool) ...	3 0 0
Dr. Wyld (London) ...	0 10 0	Mr. Bernard Roth ...	1 1 0
Dr. Wells (London) ...	1 0 0	Mr. Thomas Bond ...	1 1 0
Dr. T. Barlow (London) ...	2 2 0	(London) ...	1 1 0
Dr. Cheeseman (Bucks) ...	1 1 0	P. T. ...	1 1 0
Sir James Paget ...	2 2 0	Non Nobis Solum ...	1 0 0
Dr. Champneys (London) ...	2 2 0	Mr. A. Lansom (London) ...	1 1 0
Dr. R. Marcus Gunn ...	2 2 0	Mr. Woodhouse Braine ...	2 2 0

Further donations are earnestly invited by the Rev. H. Townshend, 41, King Henry's-road, South Hampstead, N.W. [In the list of subscriptions in our issue of March 23rd, the name "Dr. J. J. Sundell" should have been given as Dr. J. J. Swindell.]

Tate.—An M.B., C.M. who desires to be guide 11 y good taste in regard to his brass plate should put "X. Y. Z., M.B., C.M." The addition of "Physician and Surgeon" is a little more questionable, as being rather redundant. We are not prepared to say that it is wrong. It is a matter of taste. In a poor neighbourhood it may be necessary for the practitioner to make his calling clear.

"MENTAL DISTURBANCE FROM IODOFORM."

To the Editors of THE LANCET.

SIRS,—With reference to the case cited under the above heading in the last issue of THE LANCET (p. 827), I think Dr. Oldenburg is wrong in ascribing any predisposing influence to the previous epileptic attacks; for the symptoms are characteristic of acute iodoform poisoning, as has formerly been observed in a long series of cases in strong and healthy persons as well as in the weakened, at a time when iodoform was applied to wounds in enormous doses and without any discretion. It is true the acute form of iodoform poisoning is rarer than the chronic one, iodoform dissolving slowly and thus being absorbed in small quantities only at a time. But where there is much secretion or the adipose tissue abundant iodoform is readily dissolved, and acute poisoning, with psychoses of a malignant character, sometimes feigning every symptom of acute meningitis and almost always proving fatal, is very apt to set in. In these cases special care should be taken not to apply more than one drachm at a time, to discontinue its use, and to remove the remainder by syringing the wound with sterilised water as soon as the first premonitory symptoms make their appearance and the urine exhibits the iodine test.—I am, Sirs, yours faithfully,

H. OPPENHEIMER, M.D. Held., L.S.A.

Crossfield-road, N.W., April 1st, 1895.

A SIMPLE AIR-TIGHT COVER.

We have received from Messrs. Day and Co. of Weston-super-Mare specimens of their patent air-tight cover. The specimens sent consist of a piece of fine indiarubber stretched upon a circular metal frame—but any other shape can be obtained—and depends for its action on the pressure of the atmosphere. These covers form a simple and effective means of instantly making an air-tight cover on glasses, jars, cups, basins, and the like, and will preserve their contents as long as may be desired from the action of the air and from dust. In fixing the cover the centre is slightly depressed by the fingers, and thus a portion of the air in the vessel is expelled. On the pressure of the fingers being released a partial vacuum is established, and the vessel is hermetically sealed. The joint formed is so secure that a tumblers of water may be turned upside down or held up by the cover alone. For the efficient working of the cover the rim of the vessel should be perfectly smooth, and should be moistened before applying the indiarubber. Any size or shape can be obtained on application to the manufacturers.

Mr. John Boden.—The treatise on "Hyperamnia," about which our correspondent asks, is probably Dr. Wilson Fox's work on Dyspepsia. There is no special book on Raynaud's Disease besides Raynaud's own work, but the subject has been fully treated in various back numbers of THE LANCET and other medical journals. Neale's Medical Digest, gives all the references.

Mr. J. Westmorland.—It would seem that the only requirement is a fee of five dollars to be paid to one of the Boards of Medical Examiners.

CERTIFICATES OF LUNACY.

To the Editors of THE LANCET.

SIRS,—Can you or any of your readers inform me, with regard to granting a certificate of lunacy, if it is necessary to examine the patient and fill in the certificate on the same day on which the magistrate and relieving officer fill in theirs, or may the medical practitioner choose his own time for doing so?

I am, Sirs, yours truly,

INQUIRER.

* Section 29 of the Lunacy Act of 1890 requires the medical examinations to have been made within seven days of the making of the reception order; but there is apparently no other restriction as to the time at which the examination must take place.—ED. L.

AN UNDIGNIFIED PROXIMITY.

AN evening paper published in Manchester contains the following advertisements in a row:—

Manchester Eye and Ear Hospital, 25, St. John-street.—Committee: Mr. Ald. Bowes, Messrs. Chas. J. Hurst, J. T. Lingard, Jno. Lomas, J. D. Sutcliffe, and G. H. Winterbottom. Hon. Surgeon, David McKeown, M.A., M.D., M.Ch. Patients admitted on Monday, Wednesday, and Friday mornings from 9 to 11 o'clock, and on Tuesday and Thursday evenings from 6 to 7.30. No recommend is needed. J. G. Skemp, M.A., Hon. Sec.

Sufferers from Nervousness, Rheumatism, &c., should try Herr Cohen's Electrotonic Treatment, free of charge at St. James's Hall, from 10 to 5.

Ulcerated Sore Legs quickly and permanently cured by New Discovery, by Mr. Marsland, Specialist, 7, Chester-st., Oxford-rd., Manchester. Hours 2.30 to 5.30, & 7.30 to 10 p.m.

Triumphs of a Specialist.—A splendid tribute to a non-operating system. Forty-sixth testimonial published in this column. Cure of Cancer.

8, Back Moss-street, Rochdale, July 8th, 1892.

Dear Sir,—It is two years since you cured me of a cancer in the cheek. It had been growing steadily two years, and was getting very painful, and spreading rapidly. I had my attention first drawn to it by a medical man, who, perceiving the growth, asked the privilege of examining it. He pronounced it at once to be a "naughty irritating cancer." He examined it again in six months, and seemed very much concerned about it, but did not advise anything. I thought it was now time to take action, and hearing so much of you, I thought I would give you a trial. I am pleased to say that you removed it beautifully, and from that day of being discharged as cured by you it has not troubled me the least, and now you cannot see the spot where the cancer was. I consider that you made a splendid cure, for I am positive that if I had had a cut it would have reappeared and eaten my face away.—Believe me to be, yours,

Mrs. Nicol.

Mr. Whitehead, Cancer, Tumour, and Lupus Specialist. Residence: 230, Brunswick-street, near Owens College. Attendance every day 10 to 1. Branch Consulting Rooms: 21, Mawdsley-street, Bolton, attendance Tuesday and Friday, 4 to 6 p.m.; Oldham: 5, Queen-street, Monday and Thursday, 4 to 8; Rochdale: 11, Acker-street, Wednesday, 4 to 8, Saturday, 2 to 6 p.m.

We have before had occasion to point out that Dr. McKeown's private address as given in the Medical Register is that of the special hospital of which he is honorary surgeon. It is not permissible for a practitioner to advertise himself; and the advertisement of the Manchester Eye and Ear Hospital that we print above, whilst presumably advocating a charity ("no recommend is needed" must have that meaning, if it have any), in reality advances the claims of the honorary surgeon whose professional address is the same as that charity. Unintentionally no doubt on the part of Dr. McKeown, the advertisement appears at the head of a row of others of the most objectionable character.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Would you mind telling me, in your "Answers to Correspondents" next week, whether there is more than one society for insuring against accident and sickness for medical men? If more than one, which do you recommend?—I am, Sirs, yours faithfully,

SUBSCRIBER.

* The Sickness and Accident Assurance Association, Limited, of 64, Moorgate-street, E.C., offers insurance of the kind indicated by its title to professional men, and the Medical Sickness Annuity and Life Assurance Society of 33, Chancery-lane, E.C., covers the sickness risk. But we are not able to decide upon the comparative merits or competing claims of these two societies.—ED. L.

LOW FEES FOR EXAMINATION FOR INSURANCE.

THE Royal London Friendly Society intimates its intention to revise fees for medical examinations for insurances of small amount—viz., 2s. 6d. for sums not exceeding £25; 5s. for sums over £25 and under £100; and 10s. for sums of £100 and upwards. The fees, we think, are insufficient, and we advise medical practitioners to decline them.

During the week marked copies of the following newspapers have been received:—*Stratford Gazette, Derbyshire Times, Ashton-under-Lyne Reporter, Leicester Chronicle, Lancaster Standard, Essex County Chronicle, Kendal News, Birmingham Gazette, Cork Constitution, Sheffield Telegraph, Elgin Courier, Huddersfield Chronicle, Sussex Daily News, Liverpool Mercury, Midland Evening News, Liverpool Courier, Nottingham Daily Express, Stirling Sentinel Light, City Press, Bristol Mercury, Reading Mercury, Sanitary Record, West Middlesex Standard, Hertfordshire Mercury, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, Mining Journal, Builder, Lynn News, Londonderry Sentinel, Architect, Bradford Mercury, London, Times of India, Pioneer Mail, Pall Mall Gazette, Christian Leader, Walsall Free Press, Christian World, Madagascar News, Catholic Times, Surrey Advertiser, Essex Telegraph, Blackpool Times, Orchestry Advertisement, Cumberland Pacquet, Chichester Observer, Berwick Journal, Australasian Medical Gazette, Lincoln Gazette, Islington Gazette, Australian Medical Journal, Derbyshire Courier, Norwich Mercury, Scarborough Post, Dover Standard, Western Mail, Carlisle Journal, Alnwick Gazette, Somerset City News, Macclesfield Courier, Ayrshire Post, &c., &c.*

Communications, Letters &c. have been received from—

ON

THE DIAGNOSIS, PROGNOSIS, AND PROPHYLAXIS OF INSANITY.

*Delivered before the Royal College of Physicians of London on March 28th and April 2nd and 4th, 1895.*By G. FIELDING BLANDFORD, M.D. OXON.,
F.R.C.P. LOND.,

LECTURER ON PSYCHOLOGICAL MEDICINE, ST. GEORGE'S HOSPITAL.

LECTURE II.

Delivered on April 2nd.

THE PROGNOSIS OF INSANITY.

MR. PRESIDENT AND GENTLEMEN,—I have said that in many cases of insanity the diagnosis is doubtful and hazardous. When we proceed to consider the prognosis we find that our difficulties are not diminished, but if anything are increased. For the purposes of diagnosis we have to examine the state of mind of the individual at the time we see him; but to form a prognosis we have to look into the future, and to say what will happen to a patient under all circumstances—circumstances over which we may have no control, and treatment or want of treatment with which we have nothing to do. The physician called to a case of ordinary illness receives a coherent and true account of the symptoms, past and present, from the sick man and his friends or nurses. He is generally enabled by what he hears and sees to form an accurate diagnosis of the malady, and his knowledge and experience enable him to give a confident prognosis of the result, knowing well that all will be done for the sufferer that can be done, that his directions will be strictly adhered to, and that the patient himself will second his efforts and try to get well. Contrast this with a case of insanity. The patient is excited and exalted. He denies that there is anything the matter with him, scoffs at physicians and at the notion that he requires one, says he was never better in his life, and will have none of medical treatment unless it is compulsory. Or he is not exalted, but depressed; then he thinks that a physician can do him no good, that he is very wicked—too wicked to live—that his immortal soul is for ever lost, and if anyone is to do him good it is the parson and not the medical man. Another is suspicious and thinks there is a conspiracy to poison or ruin him; he is very shy of a strange medical man or of his own if he includes him in the plot, and completely refuses to take his advice. When we ask for information from the friends, what do we get? They will minimise the symptoms as far as they can; will say they have lasted a week when they have lasted for months; and all that we hear we have to look upon as doubtful and untrustworthy. When we tell them that the patient is insane we are immediately asked, How long will the insanity last, and will he recover? If told that the disorder is curable, but to effect a cure it is absolutely necessary to place the patient at once under proper restraint or in an asylum, they straightway vow that they will not hear of such a thing, that restraint means application to a magistrate and certificates and consequent publicity, and an asylum will stamp him as a lunatic, will interfere with his subsequent career, and prevent his daughters from getting married. In the face of all this we have to pronounce a prognosis upon the case, and this can only be done with a considerable reservation. In many cases, however, it is easy enough, and in these our prognosis will be unfavourable. If our diagnosis leaves no doubt about the nature of the disease, if we are sure that the patient is the victim of general paralysis, we may affirm without hesitation that he will not recover, but will die at no distant date; this verdict will often be received with incredulity by those who see a fine and apparently healthy man before them. The question of time is of great assistance to us, but is one whereon we are dependent on others for information. If we hear that a patient has been insane, and has manifested delusions or hallucinations for upwards of a twelvemonth, our prognosis will be unfavourable, and if they have existed, not for a twelvemonth, but for

No. 3737

two, three, or four years, it will be very unfavourable except in certain cases which I shall mention later. We may consider insane patients according to the various methods of classification which writers have put forward. As simple as any will be that according to the various periods of life from childhood to old age. According to this we shall pass in review patients who have inherited the malady, these being chiefly the young, others older persons who have acquired it through the dangers and ills of life. Some owe it to that change we call the climacteric, others to old age.

If we examine the insanity of children below the age of puberty, what do we find? Such insanity is rare. I put aside idiocy and the various phases of the weak-minded or imbecile children, also epilepsy or degenerative cerebral disease, the result of syphilis or injury. Children of unstable nerve-centres occasionally show symptoms of insanity at an early age, and I believe it is always inherited. It may be transient, occurring in the night, taking the form of delirium or night horrors. I have known it to be genuine melancholia, the child being much depressed, sitting alone in the dark, avoiding the society of her brothers and sisters. Yet it all passed away in a short time by removal from home and the companionship of other lively children. The prognosis here is good, but it indicates a neurotic condition which should not be overlooked. Then we come to the period of puberty, a time of profound physiological change, of great importance, not only to the female, but also to the male. There is now not only a development of the body and its functions, the procreative system, the osseous and muscular, but also of the brain-centres and mind. It might be supposed that at this time of change insanity would be frequent. It is not, however. As years advance the number of cases increases. In the Commissioners' Report for 1894 we read that during the five years, 1888 to 1892 inclusive, the yearly average of patients admitted under the age of fifteen was 323. Those between the ages of fifteen and nineteen averaged 835, while those between twenty and twenty-four were 1520. These latter are the adolescents, suffering from what has been termed the insanity of adolescence, and the prognosis in this and the insanity of puberty is equally favourable—at any rate in the females. Its character is almost always mania with excitement, exaltation, hilarious and noisy chattering and restless movement. Mr. Bevan Lewis says that, "of all the types of insanity, that occurring at the puerperal period is one of the most recoverable, yet the recovery rate is nearly as high for the insanity incidental to adolescence." And he gives the recovery rate in puerperal cases at 80 per cent., while that of adolescent females is 73·3 per cent. But, he says, "it is far otherwise with the same affection amongst men; in them, where depression is often largely present, the prognosis is far less favourable, and a wide margin must be allowed for partial recoveries, chronic incurables, and fatal cases." And he gives the recovery rate of adolescent males as 58·4 per cent. My own experience agrees with this. I have found a much larger proportion of young men remaining as a chronic residuum in asylums than of young women, and the majority of the former were patients whose insanity was melancholia, and not the noisy mania which is the characteristic form amongst the young. It would seem that the prognosis is unfavourable where the insanity does not present the characteristics which should belong to the time of life. The young when melancholic do not recover rapidly, while of acute mania at the climacteric the prognosis is bad. There is one form, however, which occurs in the young which is one of apparent depression. This has been called "acute dementia," or "acute primary dementia," or "stupor with dementia," and has been confounded with the stupor of melancholia—*melancholia cum stupore*. It is not the same; it occurs in the young, its onset is rapid, the reduction is great. We never find so rapid a reduction in melancholia. The patient appears to be in a state of fatuous imbecility, lost, dribbling, and dirty, grinning idiotically or sunk in vacuous stupor. Yet the history may enable us to give a favourable prognosis. If we find that this all came on rapidly after some shock or fright, and we can ascertain beyond a doubt that it is not secondary dementia following an attack of acute insanity, and is not a state into which the patient has gradually drifted through hereditary weakness combined with masturbation, we may pronounce hopefully as to the result even in the face of the unfavourable symptoms. The physical condition of these young people is so low that they require special treatment, warmth, food, and nursing; but with this improvement

takes place slowly but surely, and in my experience the improvement has almost always terminated in recovery.

Passing from the insanity of the young, the adolescents below the age of twenty-five, I may fitly consider that of the women, mostly young, who show symptoms of mental disorder before or after childbirth, or during the period of lactation, this being termed the insanity of pregnancy, puerperal insanity, and the insanity of lactation. All writers are agreed that the first is rare. Such cases as occur are seen by the family rather than the asylum physician, and but few are admitted into asylums. Mr. Bevan Lewis says that among 1814 females admitted only eleven cases of insanity during gestation occurred. Of these, nine had previously borne children, and no one had suffered from a previous attack of insanity. Two left the asylum recovered before their confinement, and the recoveries were in the ratio of 54.5 per cent.; two left relieved and two died, one of puerperal fever and the other of chronic phthisis. Dr. Clouston admitted fifteen in nine years to the Royal Edinburgh Asylum, and of these nine recovered, or 60 per cent. of the whole. Nine were of an acute type, seven being suicidal—a large proportion. Seven of the fifteen cases were first pregnancies and five had illegitimate children. Besides the nine who recovered, two were removed and probably got well, and two died—one from uræmic poisoning, the other from general tuberculosis. Dr. Clouston says that this form of disease in its worse forms is more incurable than the insanities of childhood and nursing. In my own experience the cases have not been severe, and, so far as I know, all have recovered. The form has always been melancholia, but not of an acute type. In mild cases the prognosis is good; but of such as are severe enough to require asylum treatment the outlook is not so favourable, and almost all are desperately suicidal. This brings me to the insanity which, albeit acute, is the most curable of all—the insanity of the puerperal period. In the majority of cases the form that this assumes is that of mania, which may rise from quiet and simple mania, with delusions, to very acute delirium. It is readily to be understood that at such a time as parturition the nerve-centres are in a very unstable condition and are ready to explode in extreme excitability. A woman, nervous by constitution and heredity, has been for nine months looking forward to and, perhaps, dreading the event. After labour, which may or may not have been easy, she is subject to the dangers of hæmorrhage, of septic contamination, and all that is attendant on uterine involution. The first thing to be noticed is loss of sleep. This is so important that I mention it here, though it belongs to the treatment rather than the prognosis. I constantly find on inquiring that the patient has slept badly ever since delivery took place. Nurses are frequently less careful than they should be as to this. They may even disturb the patient on behalf of the child, or to give food, make up the fire, or the like. They do not report to the medical attendant the little sleep the patient is having, and in a week, perhaps, mental symptoms appear, sleep is less and less or is altogether lost, and in a few days the patient is in a state of acute or subacute mania. Now if we are called to a case in this state and asked what our prognosis is, the first point to be considered is. Where is this maniacal woman going to be treated? Many such are treated at home, and it is a great thing to be able to save a young mother with, perhaps, her first child from going to an asylum. But if her friends are not able to provide the necessary nurses and medical treatment, if the sufferer is to be kept in a little stuffy room with the sun blazing into it in the dog-days, and perhaps the roar of street traffic outside, to an asylum she ought to go, and if the friends will not consent our prognosis should be a very guarded one. If everything is favourable and the patient is well cared for and has plenty of nourishment—given, if necessary, by forcible feeding—our prognosis will be good. But there are certain points to be considered. First, the age: young women recover better than those more advanced in life—e.g., those who are past the age of thirty; child-bearing in women past the age of thirty with strong hereditary tendency is certainly attended with much risk. Then will come the question of temperature. A high temperature in all acute insanity is very unfavourable, and here is especially so; for it may depend either on mere maniacal excitement or on some febrile condition of blood-poisoning, and we may have to treat not only puerperal mania, but also puerperal fever. Dr. Clouston gives us the particulars of 60 cases admitted in the Royal Edinburgh Asylum, and of these 5 died all within two

months, 4 within one month, and in all that died the temperature was over 100° F. Yet of 5 cases in which it was over 103° 3 made excellent recoveries. Mr. Bevan Lewis gives us the particulars of 68 cases, and here the mortality was 6. The mortality of Dr. Clouston's cases was 8.3 per cent., that of Mr. Lewis's 8.5 per cent. These two ratios are nearly identical, and are probably the correct proportion of deaths from the disorder. The recoveries also as reported by these two gentlemen are nearly the same. Of Dr. Clouston's the ratio was 75 per cent., of Mr. Bevan Lewis's 80 per cent. This, I need not say, is a high rate of recovery, the highest of all forms of insanity, and the reason for its being so high is not hard to discover. Such cases are all acute, most of them commencing in the first fortnight after delivery. This being the case, the patients are under medical observation and nursing, and if they are mild cases they are treated promptly and efficiently at home, or, if they are too severe for home treatment, they are at once removed to an asylum, where, with suitable care and constant feeding, they recover rapidly and surely. They do not drift on without treatment, as so many ordinary maniacal and melancholic patients do. The value of early treatment is well illustrated by these puerperal cases, even in the patients sent to asylums. These are Mr. Bevan Lewis's words: "The incalculable advantage of early treatment is very obvious in the recovery list, since of four-and-twenty who were placed in the asylum within one week of the onset of their insanity as many as thirteen were recovered within three months and the remaining eleven left recovered within five months, and this despite the fact that several of these patients had inherited strong neurotic tendencies." He tells us also that those who remained as chronic insane or who succumbed to a fatal malady were either late admissions or women over thirty years of age.

From the insanity following parturition we pass to that which occurs during the period of lactation. This may arise in two ways. It may come on at an early date after childbirth, in the fifth or sixth month, and may be due to defective uterine involution, to reflex irritation and excitement arising from suckling, or to disturbed sleep or lactation undertaken in the face of bodily illness, or it may appear later as the result of exhausting and long-continued suckling. It is not uncommon to find women nursing for months, even after cerebral disturbance has developed. Such cases occur most frequently amongst the poor and are admitted to public asylums. Yet of these the prognosis is favourable, especially of those whose insanity appears at an early date after delivery. Of Dr. Clouston's cases the recovery rate was higher than that of the puerperal, and Mr. Bevan Lewis gives one of 65.6 per cent. I myself have seen but little of the insanity of lactation in private practice, and Dr. Clouston says that of 166 ladies admitted only two were lactational cases, though there were among them the usual proportion of puerperal.

We have now arrived at the period of adult life, the period of from twenty-five years to forty-five, a period which will include many of the puerperal cases I have just been speaking of, and the largest number of patients of all kinds, for in the Commissioners' last report the average number of admissions of persons between these ages was 7,310 out of a total of all ages of 16,045. A large number of them will be found to be cases of mania, the majority of those suffering from general paralysis will also be included, and a certain proportion will be melancholic. I shall proceed to consider the cases of mania first. Under this term are comprised all the various states of exaltation, which range from a slight reduction of control to one of delusion or hallucination, and thence to a condition of maniacal delirium of the gravest nature. Now, although the last is a condition of most profound reduction, and clinically becomes a malady of the most formidable character, yet there is no absolute line of demarcation between acute mania and acute delirious mania, the latter differing from the former in intensity. The prognosis, however, will differ widely. In delirious mania the first question is, Will the patient live out the storm or die? We may prophesy that if he or she lives recovery will take place unless certain circumstances are unfavourable. In answer to the question, it may be said that young persons, and especially women, almost always recover, at any rate in the first attack. Women seem to withstand the strain of excitement and want of sleep much better than men. This will account for the large number of recoveries from puerperal mania, and the proportion of recoveries from delirious mania is, in my experience, quite as large. In thirty-six years I have lost only one young female patient from

acute delirium under asylum treatment. This one died, in my opinion, from opium poisoning, the result of hypodermic injections of morphia given, but not by my advice, at the time when these injections were first practised and were greatly in vogue. Our prognosis, then, will be favourable if the patient is properly placed for suitable treatment, if rooms and attendants are adequate, and if the latter know their business. Much depends on the patient being properly nourished, and the feeding is a matter for skilled attendants, and for them only. We do not find food obstinately resisted as in melancholia, but amateurs are not likely to succeed in giving it or in giving a sufficient quantity. There are various things to be observed before we pronounce our prognosis. The first is the pulse. If this is very quick, even when the patient is comparatively quiet, it is a bad omen. If between the paroxysms of excitement—and this is paroxysmal and periodical in almost every case—the pulse falls to a frequency not much beyond the normal we may be reassured. The tongue, too, tells its tale. Incessant shouting and talking, and the nervous excitement of the disorder, will cover the tongue with a thick, sticky coat of dead epithelium. If it increases and proceeds from yellow to brown, and brown to black, and the lips and teeth are covered with sordes, I need not say that the prognosis is bad; but nowadays, when we do not give opium and sleep is produced by drugs like chloral, chloralamide, and the bromides, this typhoid-like tongue is less often seen. Women, too, will go through a period of the most acute delirium and keep a clean tongue throughout. Then there is the temperature. It is wonderful how in many of the most delirious cases, with never-ceasing muscular movement and violence, the temperature will remain only a very little raised above the normal at 99° or 99.5°. We may find it rise to 100°, and yet not be alarmed, but if it goes beyond 100° and rises to 102° or 103° the prognosis is bad, and the patient's life is in danger. There is an acute mania where there is no delirium. Acute delirious mania runs a rapid course of a few weeks, terminating in death or, in the majority of cases, in recovery, while the noisy, garrulous, exalted state of acute mania may last for six months, a year, or even longer, and then pass away and sanity return. The prognosis points to a different issue. It is not a question of life or death; we are not anxious about the lives of these patients. The important point is, Will they recover their reason or not? Sometimes we see noisy mania varying from silly and frivolous hilarity to anger and abuse, yet without delusion, an absolute want of self-control constituting that moral insanity I have already spoken of. We inquire the duration of the attack, the history of previous attacks, if any, the condition of the patient during the interval between the attacks, the health and bodily strength, the probable cause, and the family history. The more recent the attack and the more rapid the onset the better the prognosis. If it is one of a long series of attacks and has lasted for months, we may have doubts, though sometimes patients have such attacks recurring at intervals through a long life.

The cases of simple mania with excitement are not nearly so numerous as those with delusions and hallucinations. How will our prognosis be affected by these? Delusions are no doubt evidence of a considerable reduction in the healthy action of the brain-centres. They are generally the outcome of a somewhat acute attack of insanity. If the symptoms of the latter are present, the attack having begun recently, the fact of there being delusions need not make us give an unfavourable prognosis. The attack subsides, the delusions vanish, and the patient recovers. It is wonderful how delusions vanish which have been persistently adhered to for some time. In some cases the delusions are perpetually changing. To-day there is one fancy, to-morrow another. This is a good sign. It sometimes happens, however, that all the acute symptoms subside, the patient recovers his sleep, and is able to occupy and amuse himself, but some one delusion remains obstinately fixed and becomes organised in the brain. If this goes on for any length of time, for a year or more, the individual not being melancholic, the prognosis is bad. The nature of chronic delusions varies considerably, and I am not aware that one class is more persistent than another. I have found hypochondriacal fancies very difficult to eradicate, but these are the outcome of melancholia rather than mania, and some will retain delusions of grandeur. There are in most asylums chronic patients who think themselves kings or queens, or dukes or duchesses, and will sign themselves by imaginary titles in their letters. Of course, I am not now speaking of

the exalted delusions of the general paralytic. Whenever we find these ideas of grandeur we suspect general paralysis, and then arises the question of diagnosis. If we can establish the fact that the patient is suffering from this fatal disorder beyond any doubt the prognosis follows. But occasionally the diagnosis is extremely difficult, and sometimes the most unlikely cases recover and *vice versa*.

How do hallucinations affect our prognosis? We find hallucinations of all the senses, but chiefly of sight and hearing. In an acute state of insanity hallucinations of sight are very common. Patients see visions, faces of angels, faces of devils, animals, birds, snakes, and the like, as do those who are suffering from the acute alcoholic insanity which we call delirium tremens. In the acute state other hallucinations occur also, as those of hearing, taste, and smell, or the muscular sense. But none of these need render our prognosis unfavourable. They come and they go; when the acute stage has passed away they vanish, very frequently before the delusions which accompany them. It is quite otherwise, however, with hallucinations found in non-acute or chronic cases. They are almost always those of hearing, and generally take the form of voices speaking from the next room or the next house by means of wires or telephones or some supernatural agency. If a patient who has apparently recovered from the acute state and is in all other respects restored to mental health still hears voices—not mere sounds, but words and sentences—plain and distinct, the prognosis is decidedly bad. Some lose them even after a considerable period, but these are the exceptions; and in some they vanish for a time, and then upon any failure of health return, to vanish again when the health is improved. Such patients are prone to relapses, and the prognosis is bad, for they are unstable, and there seems to be a weakness of the supreme centres which are constantly losing control.

We come now to another of the epochs of life, that known as the climacteric, an epoch of transformation when various important functions of the body with their corresponding nerve organisations come to an end, sometimes quite suddenly. When we consider what all this involves, it is not surprising that we find it to be eminently a period of nerve instability, when the various chances and accidents of life may exercise an undue influence over the nervous system, and bring about an overthrow of the mental balance. The climacteric and the cessation of the menstrual function are put down as causes of insanity. It would be more correct to say that the whole climacteric period is one of instability in which other causes, moral or physical, exercise a power which would have been resisted at another time and would have passed by without serious harm. In some cases the change of life will by itself produce mental disorder in persons prone by inheritance, or in those who have no object or aim in life, no occupation, duties, or work. What is the prognosis in these cases? The form of insanity incidental to this period of life is melancholia, more or less acute. It is an opinion common to many that the religious melancholia of this time is peculiarly hopeless and that few recover; but this is not so. The melancholia of women is almost always religious, but many recover. Comparing the statistics of various writers, we may reckon upon 50 per cent. of recoveries. In forming our prognosis we take into consideration the duration of the illness, the question of early treatment, the number of previous attacks, the health of the patient, and the cause, such as alcoholic indulgence. Many recover, but such disorder is far slower in its progress to recovery than the maniacal seizures of earlier life. There is a popular notion that the climacteric change of life will bring relief or even cure to those who are already disordered in mind, or have suffered from periodic attacks, which, it is hoped, will disappear after the new lease of life is taken up. I fear such hopes are doomed to disappointment. In my experience all such patients are not better, but worse, at the time of the cessation of menstruation, and I cannot see how such an important change and the disturbance of such functions can have a beneficial effect on an unstable nervous system. Do we find this insanity in men, and can they be said to undergo a climacteric? Assuredly there is no such functional revolution in them as in women, but they exhibit the same symptoms of mental disorder, though at a later period of life. We should fix the age at sixty-five, which corresponds to the woman's change at fifty. The mental disorder is for the most part melancholia, acute maniacal symptoms being the exception. This brings me to the consideration of melancholia in its varied aspects,

ranging from what is called *simple melancholia* characterised by depressed feeling, inability to apply to work or business or to concentrate thought, but without delusion or hallucination of any kind. The prognosis with regard to this simple melancholia is good. It may last a considerable time and pass away, leaving the patient perfectly sane and sound. There is, no doubt, at the first onset a certain risk of suicide. This is more likely to occur early than late, and should not be lost sight of. Many have these slight attacks periodically, and pass through them even without leaving home and with little medical treatment. I have often tried to cut them short by attacking that much abused organ, the liver, by giving sedatives to improve the sleep, or tonics, but seldom with much success. The disorder appears to run a certain course and to vanish in about the same time, whatever treatment is tried, or if no treatment is tried. A more advanced stage is melancholia with delusions, a more formidable but not an incurable disorder, and one which demands more active treatment—treatment which for many reasons cannot be carried out in a patient's own house amidst a number of terrified or sympathising relatives. Almost all these melancholics are suicidal; all are to be treated as such, and must be carefully guarded and kept from everything with which they can do harm to themselves. Many of them have to go to an asylum, their means not allowing the expense of taking care of them in a private house with proper attendants and the medical supervision which is requisite. A large number refuse their food and have to be fed by force, and this necessitates removal to an asylum, as such feeding cannot be carried on in a private house without a large staff. If all the proper care and treatment be arranged to our satisfaction, the patient sedulously guarded, well fed and housed, with opportunities for air and exercise, the prognosis will be decidedly favourable. Unless very old or completely broken in health, we may hold out a strong hope of a favourable termination, though the cure may take a long time. These are the cases which are cured after years of depression. In a case of mania after a year or eighteen months, the prognosis is very bad and few recover; but in melancholia so slow is the process of building up and repairing the waste of nerve-force that a year does not oblige us to give up hope. For a long time we may see no improvement at all, except perhaps in physical health; then there may be a trifling brightening which the patient will altogether deny or try to conceal, but it will go on, it may be very slowly, with perhaps occasional pauses, or even relapses, so that we must estimate it by months rather than weeks. And at last we are rewarded by recovery, and after perhaps years of gloom the sufferer returns to the full possession of every faculty, of reason, memory, and feeling, for the brain appears to have undergone no organic change. It is sad to read in the paper that this person and that have committed suicide because they were depressed when we know that all, or nearly all, might have been cured were they properly treated and guarded. The patients who suffer from simple melancholia, or from melancholia with delusions and suicidal tendency, rising even to what we may call a subacute stage, recover in large numbers and the prognosis is decidedly favourable. Not so is it in the case of those whose reduction is more severe and in whom the disorder assumes the form of acute delirious melancholia. Such persons are usually very debilitated in the beginning, and the violence of the disorder soon exhausts them. Instead of the quiet state or stupor of ordinary melancholia characterised by passive resistance and inertia we see panic-stricken frenzy and incessant motion. The patient paces the room, jumps up and down from his seat, will not lie in bed, thinks the room is on fire or he himself is going to be burned with the fires of hell. He is constantly trying to put an end to himself, will keep no clothes on, will take no food or medicine, and resists to the uttermost everything that has to be done to and for him. The strength of these people is for the most part failing at the onset and does not hold out long against the tremendous strain of this condition, complicated with want of sleep and the struggle over every dose of medicine and food that has to be given. The prognosis in these extreme cases is as bad as it can be. It sometimes happens that a patient has apparently recovered from an attack of melancholia. He seems quite well, and has returned, or is about to return, to his family and friends. All his gloom has passed away, and we are told that he has not been so well for years. He is in such good spirits, so busy and active, so full of energy and enthusiasm. This sounds very satisfactory, but as time goes on the good spirits become abnormal excitement and the energy drifts into

active mania, and we have instead of melancholia the alternate state of mania set up, and the patient has to be led through an illness of this kind. The converse also may take place, and an attack of melancholic depression may succeed one of mania. This alternation of mania and melancholia constitutes what I have already spoken of as "alternating insanity." After any attack of mania there may be a stage of depression, just as the majority of such attacks commence with depression; but this is not what I mean. In alternating insanity the patient has a well-defined period of the one form followed by a well-defined period of the other; and when he has recovered from the one, after a shorter or longer interval of convalescence, the other follows and runs its course, the two recurring with the utmost regularity, and alternating each time with almost identical symptoms through the rest of life. The prognosis of a case of this kind is extremely unfavourable. Do what we wish in the way of change, treatment, or removal of every supposed cause, the malady returns with fatal regularity. All periodicity in insanity is unfavourable. I have known patients who had alternate days of depression and excitement. This alternation went on for years with the utmost regularity, so that I could always tell the condition in which I should find the individual by referring to that which existed a week or a month ago. I have known the regularity diminish, the patient passing perhaps two or three days in the same state, but I have never known one recover. This alternating insanity is not quite the same as, though closely allied to, recurring insanity. In the latter the same kind of attack recurs after a varying interval. All insanity is liable to recur. A person who has had one attack may have another, but if the latter takes place after perhaps thirty years of health we do not call it recurring insanity. In the latter the attacks recur in rapid succession, coming on without apparent cause and running a similar course. The prognosis is unfavourable. The patients are for the most part the victims of hereditary transmission and are of middle or advanced age. It may, however, commence early, and be continued through a long life.

I have, so far, considered the various kinds of insanity, mania in different degrees, and likewise melancholia, in the different periods of life from youth to age; but besides the age of the individual and the form of the insanity, there are often other points to be taken into account, and these may have much influence on our prognosis. We may derive information and guidance from a knowledge of the cause of the disorder. For this there may be an assignable reason, a moral cause, as it is called—such as grief, worry, or overwork; or a physical, as influenza, a blow on the head, or alcohol. It may be that no cause can be assigned. In the column of the statutory statement sent with a patient we find the cause returned as "unknown" in a very large number of instances. Such insanity has been termed "Idiopathic," and if we translate this into other words it means heredity—hereditary instability—and a proneness to rapid reduction of the supreme centres through some slight cause which escapes notice or would produce no effect on a healthy brain. How is the prognosis affected by our knowledge that the disorder is hereditary? The popular idea is that such insanity is very incurable, but this is not borne out by experience. A vast majority of the cases of insanity occurring in young persons is of this kind—cases of the mania of adolescence and of puerperal mania. Parturition is not a frequent cause of insanity when we consider the number of births that take place every year. Women have children, many have large families, with no signs of insanity, therefore those who break down must have inherited an unstable organisation. Yet I have said that puerperal mania is a curable disorder, and according to the statistics a larger number recover from this than from any other form. I have found that those who are affected by inherited insanity recover, at any rate from the first attack, quite as often as others. Being unstable by nature and constitution, they are thrown off their balance by something which in others we should consider trifling, but which is sufficient to cause a reduction of their nerve centres. The reduction, however, is not deep, and recovery takes place. It is clear that such persons are liable to a return of the disorder, which any cause, slight or severe, may bring about; but in the first and possibly subsequent attacks the prognosis is good.

Passing from the hereditary or idiopathic insanity to that which is acquired by the individual himself, we have to consider, first, the "moral causes," so called. These are given in the Commissioners' Report as six varieties: (1) domestic trouble,

including loss of relatives and friends; (2) adverse circumstances, including business anxieties and pecuniary difficulties; (3) mental anxiety and "worry" (not included under the above), and overwork; (4) religious excitement; (5) love affairs, including seduction; and (6) fright and nervous shock. Now these are all called "moral causes," but some of them deserve the name of physical as much as any. The long-continued strain of the first three, which may be comprised in two words—worry or overwork,—must produce a physical effect on the brain cells and brain circulation. You will remember the experiments of Dr. Hodge and his observations on the effect of normal fatigue on the sparrow, the pigeon, the swallow, and the honey-bee. He found that the normal fatigue of the day's exercise caused a marked decrease of the nucleus of the nerve cell, and a jagged and irregular instead of a smooth and rounded outline. This was restored by the night's rest. In man excessive stimulation in the shape of overwork or worry causes a want of control of the vaso-motor system, hyperæmia, over-action of the lower centres owing to obstruction of the higher, deposits of waste, and so on. These are physical effects, though they proceed from moral causes.¹ How does all this affect our prognosis? In proportion to the time that the excessive stimulation has lasted, so will our prognosis be unfavourable or the reverse. Long protracted overwork or worry may produce the same injurious effects on the brain cells and centres as a blow or alcohol. Therefore the duration must affect our verdict. Such acquired insanity must be looked upon very unfavourably. Causes such as the sudden loss of a friend, or a fright or shock, are likely to upset an unstable mind, and to produce a rapid reduction of the mental balance; but this will not be spread over a long time, and will come nearer to that which we call hereditary insanity, and of this the prognosis is good in a first attack if it occurs in one not broken in health.

Passing to the physical causes given in the Commissioners' Report, we find some which have been already considered—as puberty, pregnancy, parturition, and the change of life. Another group is that of uterine and ovarian disorders. How far do these affect our prognosis? Under the head of uterine disorders we have to consider all the derangements of menstruation which are so commonly met with amongst the insane and are so often assigned as the cause of the mental disturbance. Of these amenorrhœa is the most common. It may occur in the course of an acute attack or have been noticed before any mental symptoms. The patient has declined in health and strength, and as concomitant symptoms the amenorrhœa and mental disorder have appeared. When by dint of rest, feeding, and sleep the bodily condition is brought again to its normal level, the catamenia reappear and the patient becomes sane—but not as cause and effect. The amenorrhœa has not caused the insanity, the restoration has not cured it, both having a more remote origin. So, too, menorrhagia may have reduced the strength and insanity has followed. If the menorrhagia is stopped the patient may recover. Neither of these conditions need make us give an unfavourable prognosis. That affections of the uterus, such as displacements, prolapse, and the like, may by a reflex irritation upset an unstable brain is evidenced by many recorded cases, and cures have followed when the uterine disorder has been remedied. The prognosis here will depend on the duration of the mental symptoms and the extent to which they have become organised. I have had a patient recover who had a severe prolapsus uteri which could not be dealt with, while another did not recover from whom an irritating pessary was removed, which was supposed to have given rise to the insanity. Though there may be amenorrhœal and dysmenorrhœal trouble in many cases, I do not think the prognosis depends on this, and examination in the case of young unmarried women is likely to do more harm than good. There is a variety of insanity which has received the name of traumatic. By this is meant insanity which is the result of an accident causing a direct blow or injury to the head, or a shock or shake to the body generally without definite harm to the head. In either case we may find insanity rapidly supervening in an acute form as the result of shock, even when the damage done to the head has been slight, and then our prognosis will be favourable if there are no other conditions to prevent recovery. I have known mental symptoms follow falls and blows and patients recover at all ages. In the young it has taken the form of acute primary dementia, and the issue

has been recovery. In elderly persons acute mania or acute melancholia has supervened, and recovery here also has followed. Far other, however, is the prognosis in those cases where the advent of the mental malady is slow and insidious, and we find at first a moral insanity, a gradual perversion and alteration of the whole man, the reduction leading to quiet and concealed delusions, or to loss of memory and incipient dementia, or to the boastfulness and other symptoms of general paralysis. All these point to a chronic organic change which the brain is undergoing and we are powerless to arrest. With traumatic insanity is often, but erroneously, coupled that which is said to proceed from "sunstroke." Sunstroke, in the strict sense of the word, rarely, in my experience, produces insanity; but heat, the continual heat of the tropics, especially in unhealthy places, produces a considerable amount. I have seen many from India, Burmah, the Straits Settlements and such climates, both men and women. I have found such patients when removed to a cold climate recover in the large majority of cases; therefore the prognosis is good. But I have come to the conclusion that those who have once broken down and become insane in the tropics ought not to be allowed to return to those climates. If they do they undergo a great risk even under the favourable conditions of hill stations in the hot weather and such-like precautions. It is not the hot days but the hot nights that try the nervous system and cause sleep to be broken and unrefreshing. More like traumatic insanity is that to which we give the name of alcoholic. Very various are the symptoms and phases of this, and the prognosis will vary equally. This is an acquired insanity, the direct result of alcoholic poisoning; but those who have an hereditary predisposition more readily fall victims, and it is not unfrequently hereditary, the same propensity showing itself in successive generations. All the varieties of insanity may be produced by alcohol. We see acute delirium and acute mania exemplified by the symptoms we call delirium tremens. Less acute than this is the insanity with delusions, either maniacal or melancholic, which is due to long-continued drinking. Now, with regard to the acute symptoms you are all familiar with them, and will agree with me that patients as a rule recover, at any rate from the first attack. Many recover again and again, and have such illnesses periodically for many years. From the less acute insanity the majority recover at first if no unfavourable conditions arise. The stoppage of the drinking allows the poison to be eliminated and the mind is restored. If the drinking is more protracted we may find evidence of organic brain change, paralytic symptoms will be noticed and signs of approaching dementia, as loss of memory and childish conversation. This is frequently the way in which the drinking of women terminates. In them delirium tremens rarely occurs, and after years of alcoholisation paralytic symptoms are often the first to be noticed. Here the prognosis is very unfavourable, yet I have known them recover in a most unexpected manner after being admitted in a helpless condition with complete loss of power in the lower extremities; but recovery of all such means a return to their evil habits, and from a second attack they are not likely to emerge. Insanity from other poisons, such as opium, chloral, or bang, is rarely met with here. Here and there we find mental symptoms, chiefly depression, coming on in persons who are addicted to opium eating, or that which is now the prevalent fashion, hypodermic injection. The prognosis is not favourable. The patient improves when the morphia is withheld or lessened, for it is not always possible to stop it altogether; but I know no habit so difficult to break through, and though many times interrupted the victim goes back to his syringe unless he is in actual confinement. Of insanity from chloral I have had little experience. If it is stopped I should expect recovery, as the habit is not likely to have continued a long time. Insanity from bang is common enough in the East, but here we do not see it. The patients recover—at any rate in the earlier attacks.

There is an insanity which occurs in epileptic patients which is of a very serious nature and is by no means uncommon. Epilepsy means a discharge of unstable grey matter, which causes mental symptoms ranging from a loss of consciousness of a very brief duration to most acute mania, or, if of long duration and much severity, to complete dementia. There are many epileptics who have fits, not very numerous or frequent, which do not produce insanity, though a certain cloud may remain for a time after an attack. But if the fits are frequent, or occur a number at a time, they

¹ Cf. Dr. Betty Tuke, Morisonian Lecture, Edinburgh Medical Journal, March, 1894.

may be followed by very acute symptoms. These may pass away, and the patient recover; yet the prognosis is unfavourable. Epilepsy in the adult is a very grave disease, of which cures are the exception rather than the rule, and the occurrence of the disease and the resulting insanity tends to that state of hopeless dementia which characterises the chronic epileptics of our asylums. If the prognosis of insanity following epilepsy is unfavourable, the outlook of that which follows apoplexy is still more gloomy. After an apoplectic seizure well-marked symptoms of insanity, mania or melancholia, may appear either at once or after an interval. They may pass away or alternate, mania and melancholia succeeding one another. But if the more prominent features disappear, there will be a weakness of mind and memory tending to the dementia so constantly found; as in all cases of organic mischief in the brain or its vessels the prognosis is unfavourable, especially in the cases of hæmorrhage, where consciousness is more interrupted than where the damage is due to thrombosis. There are many important questions, such as the degree of mind, the capacity and responsibility of the apoplectic, but I am not concerned with such at present. More favourable is the prognosis in that insanity which has been termed post-febrile, and arises in the course or towards the decline of acute disorders such as the eruptive fevers, pneumonia or typhoid fever. This is not to be confounded with the ordinary delirium so often seen, and seen when the temperature is at its highest. The insanity I am speaking of has been well described by Dr. Hermann Weber.² It does not come on at the height of the fever, but during its decline, when the temperature has fallen, and he says that the commencement in almost every case occurred immediately after waking from sleep. No doubt the brain in these cases becomes deprived of blood to a considerable extent, and on waking delirium takes place in a patient whose centres are unstable. Of this sudden insanity the prognosis is good, and the attack is usually transitory. Where insanity follows a long-continued illness, whether fever or any other exhausting malady, such as influenza, the prognosis is decidedly unfavourable, and will depend on the general health and recuperative power of the individual. I have seen several patients who had had influenza, and who never recovered. There is much difference of opinion as to the relations of syphilis and insanity. Can we speak of a syphilitic insanity? I do not myself think that insanity in the ordinary sense of the word is due to syphilis except when the latter acts as a moral cause. Syphilophobia is not uncommon. Patients who have or have had specific disease become melancholic and are possessed by the one idea that they shall die of it in its most loathsome form. Even those who have had the disease may conceive a delusion that they have it, and point to every little spot and pimple in proof thereof. Syphilis does produce mental defects, but it does so, as Dr. Hughlings Jackson has shown, "by attacking the neuroglia, the fibrous tissue, bloodvessels, lymphatics, membranes, or bony coverings, involving the nerve tissue and its functions secondarily by pressure, so causing irritation, inflammation and ramollissement, or by starvation³ from deficient blood-supply, causing degeneration and atrophy." The prognosis is most unfavourable in all cases where the brain is so damaged by syphilis, and I have rarely found that antisyphilitic treatment, which nowadays is so largely used, has produced any beneficial result. There is a form of insanity which has received the name of the insanity of masturbation on which a word or two may be said. Masturbation is very common amongst the insane, common amongst males, and also among females, though perhaps in a less degree. Amongst the latter it is constantly found in an acute attack of mania, but it disappears when the acute symptoms are over. It is not to be supposed, however, that this evil habit is the cause of the insanity in every case where it exists. In many, I may say the majority, it is a symptom. In some neurotic persons with an inherited unstable organisation it may be a cause. Loss of control allows the habit to be indulged in to excess, and the irritation and exhaustion of this perpetual indulgence upsets the weak brain and produces the mental phenomena which have been described as characteristic of this variety. These are morbid and exaggerated ideas of self, sometimes self-importance and conceit, sometimes hypochondriacal fancies about health or delusions that the patient is not sufficiently valued by his relatives and friends. At some time or other there will be an

acute or subacute attack of mania or melancholia, and when this passes away there may be a period of remission and an apparent recovery, but the patient soon drifts into hopeless dementia. The prognosis in all such cases is extremely unfavourable.

As I began with the insanity of puberty and adolescence, so will I end with that of old age. And by this I do not mean the dementia which is the last scene in the history of many a once great mind. There may be difficulty in determining the extent of this at the commencement; questions of diagnosis and of mental responsibility may arise, but of the prognosis there can be no doubt. But one meets with a certain number of cases of mania and more frequently of melancholia in old people, many of whom recover in a surprising way. The year before last I was asked to see an old lady of seventy-five years whose mental and bodily strength had been failing, as her medical man told me, for six months. She did not know where she was, though she was in her own house where she had lived for many years, and she had all kinds of delusions. Being unmanageable there she was removed to an asylum, and everyone supposed it to be the beginning of the end. She was in a somewhat acute state for some weeks, had hallucinations of sight and many delusions, and then gradually improved, became perfectly clear in her mind and memory, and went home to the old house in less than three months recovered. Dr. Clouston gives the particulars of 203 cases of senile insanity, excluding 101 others which were cases of epilepsy, mania, or dementia of long-standing or climacteric insanity. He says that heredity as a cause was uncommon. The age was from sixty to ninety years, and of these 203 persons 72 were discharged "recovered"—"that is, in all of them their worst mental symptoms disappeared, they passing into normal senility. In many cases they became quite well in an absolute sense." This is in the proportion of 30 per cent., a large number when the time of life is considered. So that our prognosis is not utterly without hope, though it may be doubtful or even unfavourable. It is to be remembered that all Dr. Clouston's patients and my own whom I have mentioned recovered in asylums. I do not think the same results would be attained by any home treatment.

Three Lectures

UPON THE

TESTES.

Delivered before the Royal College of Surgeons of England on March 25th, 27th, and 29th, 1895,

By JOSEPH GRIFFITHS, M.A. CANTAB.,
M.D. EDIN., F.R.C.S. ENG.,

ASSISTANT TO THE PROFESSOR OF SURGERY IN THE UNIVERSITY OF CAMBRIDGE; HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; ASSISTANT SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

LECTURE III.¹

Delivered on March 29th.

THE RESULTS UPON THE TESTICLE OF LIGATURE OR DIVISION OF THE VAS DEFERENS.

MR. VICE-PRESIDENT AND GENTLEMEN,—Having given in Lectures I. and II. an account of the structure of the testes at different periods of life and the influence they exercise upon the growth and development of the body, and also of the structure of the undescended testis and the function it is capable of performing, it remains for me to relate the results I have obtained from a series of experiments in which the vas deferens was ligated or divided so as to effectually and permanently obliterate its canal. I propose to give, in the first place, a short résumé of the work of previous writers upon this subject, then to show the effect of obliteration of the vas deferens upon the testicle of the puppy and upon that of the full-grown dog, and, lastly, to briefly describe a testis from a young man in whom the vas deferens had been in part accidentally removed during an operation on the spermatic cord.

² Transactions of the Medical and Chirurgical Society, vol. xlviii.

³ Dr. Clouston, Clinical Lectures, p. 420.

¹ Lectures I. and II. appeared in THE LANCET of March 30th, 1895.

Hunter² gives a full description of a case of obliteration of the vas deferens which he met with in his dissections during the year 1775. In this case, the first of its kind ever described, the vas deferens was, in the greater part of its length, converted into an impervious cord of fibrous connective tissue; but the corresponding testicle, though its duct was thus occluded and in great part obliterated, was of natural size and of normal appearance, as may be seen from the drawing which accompanies the description; and from the context there was nothing observable in the internal structure of the testicle to give rise even to a suspicion of there being any morbid changes. This observation and subsequent ones of a like nature induced Sir Astley Cooper, in the year 1823, to perform the following experiment. He said: "I divided the vas deferens [in the dog] upon the one side and the spermatic artery and vein on the other. The testis upon that side on which the artery and vein were divided gangrened and sloughed away. The testis on that side upon which the duct was divided became somewhat larger than natural. I kept the dog for six years; during that time he was twice seen in coitus, but the female did not produce. This was in 1827. In 1829 I killed him and found the vas deferens below the division excessively enlarged, full of semen, and its extremity closed; the upper portion, however, remained pervious from its point of division to its termination in the urethra. A small space was found to exist between the two divided portions."³ He made the following remark: "The testis does not in general become absorbed when partially diseased, although its functions may be interrupted, even to the complete obstruction of the passage of semen." Even after this confirmation by experiment of an anatomical observation by Hunter doubt still existed as to the accuracy of the statement. Curling in this country, and Gosselin and afterwards Godard in France, conducted a series of experiments on animals and made a post-mortem dissection in man of several instances in which the vas deferens was in part of its length obliterated. In the main their results confirmed those obtained by Cooper, as may be gathered from the following short extracts from their works. Curling concludes thus: "The foregoing cases and experiments show, then, that the testicles may be properly developed though a physical obstacle to the elimination of their secretion is present from birth; and that so long as the testicles exist entire, though to no purpose, the individual acquires and preserves all the marks of the male sex."⁴ Gosselin found the same results after excision of a portion of the vas deferens.⁵ Godard⁶ makes the following remarks: "Ainsi, l'absence congénitale du canal excréteur du sperme chez l'homme, et l'excision du même conduit pratiquée sur les animaux, donnent un résultat identique; dans les deux cas, la glande privée de son conduit se développe et fonctionne comme si elle pouvait éliminer le produit de sa sécrétion, et il est vrai que le testicule privé de communication avec les conduits éminifères ne s'atrophie pas et continue à sécréter le sperme." Thus far all the writers upon this subject seem to agree; and the results of their experimental inquiries simply confirm the inferences drawn from dissections in man. More recently, however, Brissaud examined this subject further and performed similar experiments in rabbits (not in dogs and cats, the animals previously used), and subjected each specimen that he obtained to a minute microscopical examination. Having ligatured their vasa deferentia, he divided the rabbits into two sets; the one he kept alone, and the other he placed among a lot of does, in order that the latter set might be subjected to the full influence of sexual excitement which the presence of the does was supposed to bring about. The following is a *résumé* of the results of his experiments.⁷ "En résumé, la ligature du canal déferent ne produit de phénomènes analogues à ceux des cirrhoses par l'obliteration que dans l'épididyme. Le corps d'Highmore semble opposer une barrière infranchissable à la propagation du processus inflammatoire vers le testicule. Enfin, dans le testicule lui-même tout se borne à une exagération transitoire du travail spermatogénique, à la suite de laquelle l'organe, sans retourner à l'état embryonnaire, revient à une constitution plus simple, celle de la neutralité fonctionnelle, c'est-à-dire celle qui précède son développement complet ou qui correspond aux intervalles des époques du rut."

While residing in Paris in the summer of 1890 I began, through the kindness of Professor Dastre, of the Experimental Physiological Laboratory of the Sorbonne, to whom I am much indebted, a series of experiments on the testicle in dogs, and have since conducted some at Cambridge. I made use of puppies and of full-grown dogs. In most instances, after exposing the spermatic cord in the groin I opened the processus vaginalis and seized the vas deferens and ligatured it with a piece of strong sterilised silk; in others I made use of two catgut ligatures and divided the cord between them. The wounds as a rule healed by first intention, and when they did not there was only a superficial wound left to granulate, which did not interfere with the dog running about and appearing as lively as ever. I will give an account of only a few of my experiments and will group them for convenience under the following headings: (1) ligation of the vas deferens in puppies; and (2) ligation of the vas deferens in full-grown dogs.

1. Ligation of the Vas Deferens in Puppies.

CASE 1.—A fox-terrier puppy about two months old. On June 28th, 1890, the right vas deferens was tied in the inguinal region with sterilised catgut. On the following day no change was observed in the corresponding testicle. On July 1st, three days later, the dog was killed. The right vas deferens was completely occluded, but there was no difference between the two testicles. After hardening in spirit no change whatever between the two testicles could be detected by the microscope.

CASE 2.—A puppy sheep-dog about four months old, whose testicles were as yet small and undeveloped. On Dec. 29th, 1890, the left testicle was removed, and the right vas deferens was ligatured just outside the inguinal ring with sterilised silk thread. There was no change in the testicle after the operation, and both wounds healed rapidly, the animal soon getting well. In the beginning of April, 1891, the testicle (right) began to show signs of growth, and it grew rapidly until at the end of the month it was of nearly natural size. The animal was killed. This right testicle is illustrated in Fig. 17, because it shows in a remarkably clear manner the

FIG. 17.

Right testis of dog. (Experiment 1.) Body of testis somewhat globular in shape, epididymis much enlarged from distension of its tubules, and vas deferens distended up to seat of ligature.

changes that arise after a certain period in the epididymis, and also those in the testicle, the latter being much less marked. The epididymis is greatly swollen, the lobules of the upper part being especially prominent, as are also the convolutions of the duct below, though these are not so well represented in the drawing. This enlargement of the epididymis, and indeed of the vas deferens, up to the seat of ligature is dependent upon over-distension due to the accumulation of the seminal fluid secreted by the testicle. The body of the testicle had assumed a globular shape, thicker and somewhat more tense than a testicle the secretion of which is allowed to pass away freely. Under the microscope this testicle presents the appearance of a perfectly healthy active gland; and in the epididymis the only changes are those of dilatation of all the tubules, their cavities being filled with seminal secretion abounding in well-formed spermatozoa.

2. Ligation of the Vas Deferens in full-grown Dogs.

CASE 3.—A large sheep-dog from three to four years old. On June 24th, 1890, the left vas deferens was tied in two places and divided between them. On the following day (25th) the left testicle and epididymis were slightly swollen and tender. No unusual sexual excitement was noticed in this case, and no further changes were observed. The animal was killed on July 1st, seven days after the operation, and the organs were placed in strong spirit. Under the microscope the seminal tubules appeared normal, showing the natural formation of spermatozoa. In some tubules there were many small, round homogeneous bodies of about the size of red blood-corpuscles; these stained of a delicate pink colour with carmine and are probably of the nature of mucin bodies. The tubules of the epididymis contained spermatozoa, and showed no signs of a structural change in the epithelium or in the intervening connective tissue.

CASE 4.—A fox-terrier eighteen months old. On Oct. 30th, 1890, the left vas deferens was ligatured with sterilised silk thread in the groin. The wound healed quickly, and the animal was soon well and running about. On the following day, Nov. 1st, the testicle as well as the epididymis was enlarged and tender; this passed away, but reappeared on Nov. 10th; and on Dec. 20th the testicle was apparently smaller, firmer, and more tender than natural. No further change took place until Jan. 22nd, 1891, eighty-three days after the operation, when the animal was killed. The epididymis, as also the vas deferens up to the seat of ligature, was found distended, though not to any great extent, but the body of the testicle presented nothing abnormal in shape or size. Microscopically the testicle is quite normal, the seminal tubules being well formed, showing abundance of spermatozoa in their interior, and the process of spermatogenesis could be traced in most of them. In the epididymis the epithelial cells lining the over-dilated tubules have lost their tall columnar character, and are reduced to low cubical cells which do not bear cilia as do the natural columnar cells. Further, the cells thus flattened are found in several layers; the walls of the tubules are unaltered, and the intervening connective tissue remains unchanged and free from any signs of inflammation. (Fig. 18.)

FIG. 18.

Section of epididymis of a dog after ligation of vas deferens. $\times 35$.

Accordingly, when the vas deferens is ligatured in puppies there is no immediate result either upon the epididymis or testicle; nor is the growth of the latter in any way interfered with—that is to say, the ligation of the duct does neither hasten nor retard the growth of the gland, and the testicle acquires its maturity both of structure and function just as if the duct had been left alone in its natural and previous state. Again, when the vas deferens is ligatured in full-grown dogs there occurs enlargement of the epididymis, with tenderness. This enlargement in part subsides, leaving it, together with the portion of the duct up to the seat of ligature, permanently enlarged from the accumulation of semen. The structure of the seminal tubules remains unaltered, and they are after a few days or a few months just the same, showing the active formation of spermatozoa, as those of the normal testis, the duct of which is left natural and undisturbed; therefore ligation of the vas deferens induces a slight enlargement of the epididymis and of the vas deferens up to the seat of ligature,

but it does not interfere in any way with the structure of the seminal tubules or the production of spermatozoa. This is in accordance with the views of Hunter, Cooper, Curling, Gosselin, and Godard, and in part with those of Brissaud. Curling and others, who were aware, both from experiment and observation, of the independence that exists between the growth of the testicle and that of its duct, considered that this independence was due to the manner in which the testicle and vas deferens took separate origin in the embryo. It is now generally well known that the testicle arises from a modification of the germinal cells of the body cavity, while the vas deferens (Wolfian duct) is either a segmentation from the epiblast near the dorsal groove or takes origin in the intermediate cell mass as a solid rod which soon becomes hollowed into a tube or duct, and subsequently these two become united by the development of intermediate tubules which form the vasa efferentia, and which effect a communication between the numerous seminal tubules on the one side and the canal of the epididymis on the other. Accordingly, the testicle and its vas deferens have each of them, like the kidney and its ureter, a separate origin in early embryonic life, and in this respect they differ from other glands. It may be questioned, however, whether this is really an explanation of the fact that when the vas deferens is ligatured or in great part destroyed by disease the testicle grows to its full size and acquires its function as if there had been no interference. Such an explanation as that adopted by Curling, attractive as it may seem, is not only unnecessary but probably erroneous, and some other reason than independence of origin in development must be sought for. Up to the time of adolescence the testicle and the vas deferens constitute together an unused apparatus which simply grows gradually in each of its parts preparatory to the greater development at puberty; and the whole genital system is an apparatus the potentiality of which mainly depends upon the integrity of the testicles, one or both, and that they control the extent to which the remainder of the sexual apparatus grows, the growth of the vas deferens no less than that of the prostate and other accessory sexual glands. I make this statement because in observations upon castrated animals I have found that the testicle exerts (see Lecture I.) such an influence upon the growth of the other parts of the sexual apparatus, while I have found nothing to indicate that any other part of this apparatus exerts even the slightest control over the growth of its neighbour or over that of a distant part. When, for example, the vas deferens is, either in part or in the entirety of its length, destroyed the testicle and the remainder of the apparatus on that side of the body, including the vesiculae seminales and prostate, continue to grow without any observable modification until they reach their full size. Further, it is not until that full size is attained and the functional powers of the gland as a secreting organ are well established that any imperfection resulting from the obliteration of the vas deferens becomes manifest except such as I have mentioned. Therefore any injurious influence which that obliteration may give rise to may reasonably be inferred to be the result of interference with the due expulsion of the semen from the gland and of its accumulation in the part of the duct still unobliterated.

It may be observed that in other organs, where the duct is occluded by disease or otherwise, the secretion as it is formed is prevented from making its proper escape, accumulates, and in time, if not small in amount and absorbed, tells injuriously upon the secreting tubules. For example, ligation of the biliary duct induces a variety of cirrhosis of the liver if the obstruction be permanent and complete, as shown by the researches of Wickham Lezg and afterwards by Charcot and others; and this change follows in virtue of the damming up of the bile, first in the biliary ducts and ultimately in the bile capillaries, the secretion of bile going on more or less continuously until the liver cells become destroyed by the pressure of their own secretion. In the testicle, however, the same result does not usually follow except to some extent in the epididymis. May not this result either from the great length of its tubules and the slow secretion of spermatozoa or from the absorption of the seminal fluid taking place in proportion to its rate of secretion? This view seems to be on the whole confirmed by the observations of Brissaud in the rabbit and of myself in the dog and in man. Brissaud, it may be remembered, obtained, after ligation of the vas deferens, different results according to the conditions under which the animals were placed after the operation. For example, if, on the one hand, the rabbits operated upon were placed by themselves, nothing more than a passing enlargement of the epididymis and

testicles occurred, similar to that which has been shown above to occur in full-grown dogs; but if, on the other hand, they were placed with does different results occurred—results in which the structure of the testicle becomes like that of a testicle before its full development at puberty or during the non-rutting period of rutting animals. In the latter series the testicle passed through a period of super-activity that was followed by certain atrophic changes in the structure of the seminal tubules, and by means of these changes the testicle becomes transformed into the state above referred to. It seems clear, therefore, that Brissaud found some atrophic changes in the testicle consequent on his experiments. I can, however, scarcely agree with his statement that these changes correspond with the condition before puberty or with that in the non-rutting period of rutting animals. But I would note that the structure of the testicle under these conditions, as gathered both from the description and drawing given by Brissaud, does not quite bear minute comparison with that either of the undeveloped organ or of one of a rutting animal during the non-rutting season. In the rabbits that were subjected to the sexual influence of the does the testicle represented by him shows that the seminal tubules were much reduced in size, and the epithelial lining of the interior was in many places represented by a single layer of small cubical cells surrounding a rather large central lumen; the intertubular connective tissue was increased, and in some places it was denser and more fibrous than natural, whereas in the undeveloped organ—twenty or more of which I examined—the seminal tubules were in all instances solid rods of epithelial cells, and I also found this to be the case in the testicles of rutting animals during the non-rutting period, as has already been pointed out in Lecture II. Further, the amount of intertubular connective tissue or stroma is not in increased quantity. The essential histological features, therefore, of the two conditions differ, and the two states are distinct from one another.

CASE 5.—A hound from eight to nine years old. On June 11th, 1890, the right vas deferens was ligatured with sterilised catgut and the left testicle removed. The wounds healed quickly, and but little change occurred in the right testicle for three or four days except for some tenderness, especially of the epididymis. On June 16th there was great sexual excitement, erection of the penis being more or less constant during the day, and the parts were tender. On June 18th swelling of the lower end of the epididymis became distinct, and sexual excitement, though somewhat less than on the previous days, was yet strongly marked. On June 25th the testicle itself was found to be appreciably reduced in size and softer than natural, but not nearly so tender as it was a week previously; the epididymis still remained of large size.

FIG. 19.

Testes of dog (Experiment 5) twenty-one days after ligature of right vas deferens. Left testis of full size. Right testis considerably reduced in size.

The testicle became gradually less in size, and it acquired a more globular shape than natural. On July 2nd the dog was killed, and the organ was placed in strong spirit. The body of the left testicle, which was removed when in a healthy state, is ovoid in shape, measuring 30 mm. in length and 17 mm. in breadth; while that of the right, the duct of which was ligatured, is less and of a more globular shape, measuring 25 mm. in length and 14 mm. in breadth, a difference which indicates a considerable diminution in entire

bulk (Fig. 19). The epididymis, however, is enlarged, especially at its lower end, the upper part, or head, and the body having during the last week or so become considerably diminished, owing probably to the disappearance of the secretion that had overfilled its tubules. In this (the right) testicle the seminal tubules are much reduced in size and in number, but the intervening connective tissue is not much, if at all, changed. The tubules, of which none are normal, show different degrees of wasting; those tubules that are least changed have a thickened tunica propria lined by a single layer of small cubical cells, the middle of the tubules being occupied by larger and irregularly shaped cells which do not show any traces of the formation of spermatozoa, whereas those that exhibit the most advanced changes have a much thicker tunica propria, and the epithelium in their interior is reduced in most instances to a single layer, which is of the columnar variety. These columnar cells rest with their bases or outer ends upon the altered and thickened tunica propria, and their inner ends taper towards the centre and occupy the middle of the tubule, as seen in Fig. 20. The tunica propria is divisible, when much thickened,

FIG. 20.

Section of right testis of dog. (Experiment 5.) Seminal tubules with thickened tissue lined by a single layer of tapering fibrillated columnar cells.

into two layers—an outer thin layer of connective tissue, resembling the original tunic, and an inner, more transparent one, with wavy fibrils traversing it. This inner layer seems as if it had been formed from the connective tissue of cells of the normal tunic which had remained more or less unaltered. In the epididymis the muscular coat of the tubules is infiltrated with connective-tissue cells, and the intertubular stroma is increased and denser than natural, but the epithelium of the tubules is hardly altered.

Similar results occur in man, as shown by the following specimen, the only one that I have obtained in which the vas deferens was occluded. The testis was excised from a young man, managed twenty-one years, six weeks after the removal of an encysted hydrocele of the cord with which had been taken away a portion, about three-quarters of an inch in length, of the vas deferens. After the hydrocele had been removed the testis, which was previously normal, swelled and became tender, and owing to the continuance of the pain and tenderness the organ was excised at the man's request. The body of the testis was of about the natural size, but firmer; the epididymis was somewhat enlarged, the tubules being distended, and the tunica vaginalis showed signs of previous inflammation. The seminal tubules were reduced in size and in number, and the intertubular tissue was relatively increased. In none of the tubules could the natural arrangement of the seminal cells be seen; and in none of them were there any evidences of spermatozoa or of spermatogenesis. In the tubules that were the least changed the seminal cells were represented by a single layer of small cubical cells at the periphery of the tubules, and a number of irregularly shaped cells occupying the lumina (Fig. 21). In the tubules that were much reduced the seminal cells were represented by a single layer of columnar cells enclosing a small central lumen. In these tubules the tunica propria was not much altered, but between it and the epithelial cells there was a thick layer of almost transparent fibrillated connective tissue which arose from the inner cells of the tunica and took the place of the receding and dwindling epithelial cells. In a few tubules the epithelial cells had completely disappeared, leaving a narrow fissure-like lumen, the two parts of the tunica propria only representing the tubule. The stroma

consisted largely of cellular connective tissue, with here and there a considerable formation of a fibrous matrix. The tubules in the epididymis were not much altered, and the intertubular connective tissue was natural. Thus the changes that occurred in this specimen were practically identical with those in the preceding one from a dog.

Are these changes dependent upon simple ligation or severance, or are they the result of some damage to and subsequent interference with the blood flow through the spermatic vessels? Seeing that ligation of the vas deferens may be practised on full-grown dogs over and over again without producing any destructive changes in or atrophy of the seminal tubules, and seeing that the testis is usually natural in cases where there is a congenital deficiency of the duct in man, it is but reasonable to suppose that there exists some

FIG. 21.

Section of right testicle of a man, aged twenty-one years, six weeks after removal of a portion of the vas deferens with an encysted hydrocele of the cord. $\times 450$. *a*, Tubules lined by a single layer of columnar tapering cells. *b*, Thickened tunica propria.

additional cause when progressive atrophy of the seminal tubules occurs. It is, I believe, true that in the human subject atrophy of the seminal tubules not infrequently follows the removal of cysts or growths of the spermatic cord in which the vas deferens is accidentally ligatured or a part of it excised; but in these cases the tumours or cysts arise from the middle of the cord, and as they grow they spread out the structures (the vessels and nerves) of the cord upon them; accordingly, when such tumours or cysts are removed the spermatic vessels and nerves have to be carefully dissected off, and during this process I apprehend that damage is done to them. When, therefore, a portion of the vas deferens is accidentally removed under the above circumstances the testicle is influenced, not only by the results of the damming up of its secretion, but also by the damage done to its bloodvessels in the spermatic cord. It would hence seem that mere division, ligation, or occlusion of the vas deferens does not lead to atrophy of the seminal tubules; but if in case of division there is, in addition, some damage to the other structures of the cord destructive changes, followed by atrophy and ultimate disappearance of the seminal cells, are liable to occur.

With regard to the suggestion made by Mr. Reginald Harrison of division of the vas deferens in cases of enlarged prostate I have not sufficient experience to arrive at a conclusion; but, seeing that obliteration of the vas deferens has so little effect upon the structure and secretion of the testis, it must be doubtful whether the operation will suffice to influence the enlargement of the prostate.

INTERSTITIAL KERATITIS AND SYNOVITIS, WITH REPORT OF A CASE IN WHICH BOTH WERE UNILATERAL.

By G. CRAWFORD THOMSON, M.D. DURH.

(Continued from p. 861.)

Interstitial keratitis and inherited syphilis.—I am aware that to some authorities the coexistence of interstitial keratitis and synovitis, to others even the existence of interstitial keratitis alone, will be sufficient for the diagnosis of syphilis, even if there is no other evidence in the condition of the patient, in his previous history or that of his relatives; but, as far as I have been able to ascertain, the present position of the question, judged from the results of the most reliable observers, does not justify these rigorous conclusions. This statement is in antagonism to another rule laid down by Hutchinson¹: "Interstitial keratitis in its typical form is always a consequence of syphilis and in itself sufficient for the diagnosis." But, as shown by a table of statistics recently published by Dr. G. Ogilvie,² the results of most other ophthalmic surgeons do not bear out the above rule. The highest percentage was found by Parinaud (96.7 per cent. in the comparatively small number of thirty-two cases), but he also admits that the corneal lesion has nothing specific and is observed outside syphilis.³ Nettleship, amongst 240 cases, found evidence of hereditary syphilis other than corneal disease in 68 per cent., and in the remaining 32 per cent., almost without exception, strong suspicion.⁴ The 68 per cent. of cases with other syphilitic symptoms are in accord with other observers, while the 32 per cent. of suspicious cases are considerably in excess of the results of others. But here much scope is left to the individual interpretation of facts. The polymorphous character of inherited syphilitic lesions is well known, so is the fact that not one of them is really pathognomonic; therefore, two, or even more, symptoms met with in syphilis might coexist without being produced in a particular case by that disease. Snuffles and a rash on the buttocks exactly imitating the specific form, appearing about six weeks after birth, are not sufficient for the diagnosis.⁵ In the same way any other symptom met with outside inherited syphilis, even if complicated by interstitial keratitis, will also not be sufficient proof, and it is here where the individual judgment of the observer plays a rather arbitrary part. Therefore, statistics drawn up by different observers cannot safely be compared unless the principles on which they are based are practically the same. This condition is fulfilled in the statistics I am now going to quote. The percentage generally found, if drawn from a sufficient number of cases, is between 60 and 70: Ancker, 61 per cent.; Horner, 70.5 per cent.; Fournier, between 70 and 75 per cent.; Jakowlena, 57.1 per cent.; Saemisch, 63 per cent.; Wecker, 66 per cent.; and Pfister, 64 per cent. Panas,⁶ combining the numerous statistics on the subject, finds the average to be from 40 to 41 per cent., but this is decidedly too low and probably due to non-comparable statistics being compared. Fournier,⁷ also granting the part which hereditary syphilis plays in the production of interstitial keratitis (in 212 cases of hereditary syphilis he saw 88 of interstitial keratitis), says: "It is incontestable that interstitial keratitis is met apart from any specific influence" (p. 218); and: "Interstitial keratitis is neither cachectic, nor scrofulous, nor a syphilitic lesion, but 'une lésion vulgaire banale,' a simple lesion of nutrition which can be produced by different morbid influences" (p. 218).

Another argument against the exclusively specific nature of interstitial keratitis, given by Ogilvie, is that it has been observed in dogs, and experimentally produced in rabbits. Since the publication of his paper several cases of interstitial keratitis have been observed in bears by Hennicke,⁸ and the diagnosis has been confirmed by microscopical examination,

which, besides diffused interstitial inflammation of the cornea, revealed inflammatory changes in the ciliary body and in the equatorial regions of the choroid. Oglvie's argument is exactly the same as the one adduced by Hutchinson⁹ for the non-syphilitic character of rickets and scrofula: "That rickets and scrofula are both of them frequently met with in the lower animals, and that they may, indeed, be produced artificially under conditions which make the influence of syphilis an impossible hypothesis." Again we find Mr. Hutchinson referring to the fact that miscarriages are abundantly frequent in our domestic animals in order to prove that the influence of syphilis in the production of abortion is probably overrated;¹⁰ and protesting against the condition known as the macerated foetus being accepted as an indication of syphilis, he also takes his argument from the fact that nothing is commoner than the macerated lamb, calf, or foal (p. 416). If this argument holds good for rickets, it holds good as well for interstitial keratitis, and then the experiments of Wagenmann, to be referred to later, and the observations of Haltenhoff, Randolph, and Hennicke disprove the exclusively specific character of interstitial keratitis.

According to Fournier¹¹ four theories exist concerning the causation of interstitial keratitis: (1) that it is a cachectic malady—"une manifestation de la misère organique" (Panas); (2) that it is produced by scrofulous or strumous disease (W. Mackenzie); (3) that it is exclusively, or nearly exclusively, due to syphilis (Hutchinson); and (4) that it is a lesion of general nutrition (Fournier). He dismisses (2) with little comment, as no connexion with strumous disease could ever be proved; he considers (3) to be contrary to the clinical facts, as interstitial keratitis is met with apart from any specific influence; and refutes (1) because interstitial keratitis is met with in subjects otherwise apparently healthy, and in private as well as in hospital practice. I fail to see that Fournier's explanation differs materially from that of Panas. "A lesion of general nutrition," "cachexia," and "organic misery" are only different expressions for the same condition or for different degrees of the same condition. Therefore, the fact that interstitial keratitis is met with in apparently healthy subjects is explicable by either theory only in one and the same way—viz., that the defective general condition in these cases is apparent as localised or limited to one special organ. This same view has been quite recently taken by Panas,¹² who admits that between Fournier's dyscrasia and his cachexia practically no difference exists, and that he therefore willingly accepts Fournier's denomination instead of his. From the above the conclusion has to be drawn that in the production of interstitial keratitis hereditary syphilis is probably operative in between 60 and 70 per cent.

With regard to the affection of the joint we have no similar statistics to be guided by, but that the appearance of interstitial keratitis, with or after effusion into the knee-joint, need not be in itself conclusive proof of hereditary syphilis has already been suggested by Foerster. Arlt¹³ has seen this painless and benign knee affliction in ten cases of interstitial keratitis, all of them non-syphilitic. Laverne¹⁴ has put together fifty cases of interstitial keratitis. Syphilis was absolutely certain in nineteen cases, very probable in thirteen, probable or doubtful in twelve, and could be excluded in six. He mentions only one case of effusion into the knee-joint, and this case is to be found amongst the six in which he excludes syphilis. I, therefore, from my own case as well as from the experience of Arlt and Laverne, draw the following conclusions. Neither interstitial keratitis nor the synovitis, nor their coexistence, is in itself absolute proof of hereditary syphilis; that the joint disease also is due to a general defect in nutrition, in the production of which inherited syphilis plays a prominent part, the extent of which we are not able to give in figures. In what this disturbance of general nutrition consists, what general condition constitutes the connecting link between interstitial keratitis and synovitis, is merely a matter of conjecture. But some light will perhaps be thrown on this point afterwards by reference to the pathology of interstitial keratitis.

Interstitial Keratitis and Rheumatism.—Obscure as is the connexion between the two affections, interstitial keratitis and synovitis, it is certainly not produced

by rheumatism, although this interpretation has been given to their combined appearance by writers here and abroad. Undoubtedly the existence of swollen joints was regarded as evidence of rheumatic disease without taking the other possible causes into due consideration. If in the causation of interstitial keratitis acute rheumatism played any part this fact would be referred to in the text-books on this disease of everyday occurrence; but in not one of the leading English, German, or French works on rheumatism can we find mention of it. Mitchell, Bruce, and Senator do not refer to eye complications at all; according to Homolle the visual organ is not affected in acute rheumatism; Charcot says that affections of the eyes in acute rheumatism are exceedingly rare; Besnier that the eye enjoys a nearly complete immunity from disease; and Archibald Garrod that the eye is little liable to be attacked in the course of rheumatic fever. All give as the only ophthalmic complication a troublesome conjunctivitis in no way characteristic, and probably identical with what is met with in other fevers. The eye itself is not attacked, with the only exception of the superficial vesicular form of keratitis consisting in the elevation of the epithelium in small blisters and superficial ulceration after their bursting (Terrier).¹⁵ This keratitis is met with occasionally in any febrile disease with predilection to affections of the respiratory tract, from a simple cold to a pneumonia, and, being frequently accompanied by herpes of the lips, with which it is pathologically identical, has been properly called "herpes of the cornea" (Horner). In subacute and chronic rheumatism, however, eye affections are by no means rare (Bennett, Watson, Garrod, Fuller, Cornil, Charcot, Besnier, Hutchinson, Homolle, and others). The lesions observed are iritis, cyclitis, scleritis, and episcleritis; but nowhere is interstitial keratitis given as a rheumatic complication. From this fact alone the cases of interstitial keratitis published as of rheumatic origin have to be received with considerable suspicion. By some Foerster has been represented as having first demonstrated the rheumatic origin of interstitial keratitis, although he wishes the difference between the joint affection described by him and the rheumatic to be clearly understood. Spencer Watson, in a paper already referred to, gives four cases of interstitial keratitis associated with synovitis of the larger joints (knee three times, elbow once), which he ascribes to acute rheumatism. Apart from there being strong evidence of hereditary syphilis in at least three of them, the acute rheumatic nature of the synovitis is not proved in one, there being, for instance, no notes as to temperature. Instead of questioning, as Mr. Watson does, "whether the keratitis of inherited syphilis is not a form of rheumatic ophthalmia," it would have been more to the point to inquire whether the form of synovitis met with, the keratitis of inherited syphilis, was not of other than rheumatic origin. A remarkable and perhaps unique case under the care of Dr. Armstrong of Newcastle-on-Tyne has been reported by Maynard.¹⁶ The patient was suffering from severe interstitial keratitis, and had a clear history of congenital syphilis and effusion into both knee-joints, ankles, wrists, and finally elbows. Although the sweating and rise of temperature were in favour of rheumatic joint disease, Dr. Armstrong is inclined to attribute the joint affection to syphilis, on the ground of the rapidity and long duration of the effusion, the absence of redness of the skin, the relaxation of the ligaments with increase of mobility, and the previous history. But whatever view may be taken of the nature of the joint affection, the interstitial keratitis is sufficiently explained by the evidence of hereditary disease, and cannot be put down to rheumatism. Couzon¹⁷ mentions that he has seen two or three cases of interstitial keratitis without any trace of syphilis, but with rheumatic articular manifestations which disappeared with the keratitis. Of these cases he reports only one. This case, also referred to by Perinaud,¹⁸ is the only one I could find in which the connexion between rheumatism and interstitial keratitis has been established with some probability. But as nothing else is known about the connexion between rheumatism and interstitial keratitis, the case has to be regarded as an exceptional coincidence rather than as one proving a pathological connexion otherwise not borne out by clinical experience.

The coexistence of interstitial keratitis with synovitis has led to the erroneous diagnosis of rheumatism, a mistake which might be avoided by a more careful investigation of the nature of the joint affection and by a less vague use of the word "rheumatic." The connexion between rheumatism and interstitial keratitis as cause and effect has neither been established by the experience of general medicine nor by that of ophthalmology in special.

Pathological anatomy and pathology of interstitial keratitis.—It is self-evident that a disease with a decided or almost invariable tendency to recovery only rarely presents itself for anatomical examination. No example of a typical uncomplicated case of interstitial keratitis has yet come into the hands of the pathologist. The cases which have been examined were the rare exceptions of malignant destructive character, and were seen at a stage when the actual inflammatory process had led to considerable consecutive changes such as cicatrization, perforation, glaucoma, &c. Besides, amongst the cases which, from a pathologico-anatomical point of view, have been described as interstitial or parenchymatous keratitis, some have absolutely nothing to do with the disease in question, being instances of diffused corneal affection brought on through general disease of either the whole globe or the anterior part of it, sometimes of tuberculous, sometimes probably of embolic, origin. This remark applies first of all to Virchow's¹⁹ case, which is constantly quoted as the first case of interstitial keratitis examined microscopically. After an intense diffused phlegmonous inflammation of the extremities, which ended fatally, the cornea became affected (the patient was under the care of von Graefe). It is more than likely that the purulent inflammation of the eye, of which the corneal affection was probably only part, was caused by some embolism from the destructive changes going on in the lower extremities, and that the case ranks with those of metastatic or embolic choroiditis, subsequent to puerperal or other septic processes. The second case usually referred to is that of Kruckow.²⁰ Both eyes were removed a few hours post mortem from the body of a woman aged forty-eight years, the subject of old acquired syphilis, who died from large gummatous tumours in the brain and petrous portion of the temporal bone. The information given on the localisation of the disease and the microscopical changes of the corneal tissue is very scanty; anyhow, double keratitis in acquired syphilis at the age of forty-eight years, if interstitial at all, must be considered a most exceptional case, and not one from which conclusions can be drawn on the ordinary form. A much fuller description of the anatomical changes is given by Baumgarten.²¹ But here, too, the clinical history has nothing in common with what is properly called interstitial keratitis, and the case is therefore rightly described by him as one of "sclerosierende keratitis," meaning an inflammation of the cornea in which it assumes a sclera-like appearance. The patient was sixty-three years of age, a time of life at which interstitial keratitis is practically unknown. O. Meyer²² quotes the last two cases mentioned as the only two examined histologically which with full certainty can be considered as typical specimens of interstitial keratitis (p. 5). As said above, the last case can under no circumstances be so classified, presenting a rare affection clinically absolutely different to interstitial keratitis; while Kruckow's case is at least doubtful. His own case, regarded by him as the third of undoubted interstitial keratitis examined anatomically, is subject to doubts as grave as in the other cases. The patient, who was under the care of Dr. Swanzy in Dublin, had phlyctenular ophthalmia when twenty years of age, circumscribed scleritis a year later, and five months after that on the inner surface of the cornea a yellowish white deposit began to form without any inflammatory redness of the globe. It spread from its original seat gradually over the whole posterior surface of the cornea, and while the process was going on, absorption of the exudation began at the starting point, so that it had disappeared there when it had reached the opposite side, leaving a diffused opacity behind. In my opinion, taking the clinical and anatomical observations together, it is most probable that some tuberculous process involving the anterior part of the globe had led to secondary infiltration of the cornea. Von Hippel, jun.,²³ has described the case of a boy, probably subject to

hereditary syphilis, who had been under treatment for parenchymatous keratitis with iritis for several weeks. He died from laryngeal croup. The changes found in the cornea were vascularisation and a rather typical cellular infiltration, as well as inflammatory changes in all parts of the eye, presenting themselves partly under the form of typical giant cell tubercles without caseation. To this case exactly the same remarks are applicable as to the former. A case of undoubted interstitial keratitis under the care of Hirschberg, and described by him as malignant diffuse keratitis, had led to glaucoma, enlargement of the globe, cornea globosa, complete cicatrization of the latter, in fact, to total disorganization of the eye, when it was examined by Birnbacher.²⁴ Another case, undoubtedly due to hereditary syphilis, and microscopically examined by Mr. Nettleship,²⁵ although interesting enough in itself, especially as far as the fundus of the eye is concerned, is not conclusive with regard to the anatomical condition of the cornea in interstitial keratitis, because it was complicated with trauma of the cornea. The patient was under the care of Mr. Brudenell Carter, suffering from interstitial keratitis with iritis, when the left eye was ruptured by a poke from an umbrella stick.

Up to the present date pathological anatomy supplies us with scarcely any information as to the histological process underlying the clinical aspect of interstitial keratitis. Out of seven cases quoted above, which, according to my knowledge, constitute the complete list of cases diagnosed as interstitial keratitis, and examined microscopically, four—those recorded by Virchow, Baumgarten, Meyer, von Hippel—cannot clinically be considered as specimens. Kruckow's case is, at least, doubtful and rather incomplete. The two undoubted cases are not conclusive for the reasons given above; one (Birnbacher) because it was examined at too late a stage, the second (Nettleship) because it was complicated by injury; therefore the greater value seems to me to be attached to the researches of Wagenmann,²⁶ who succeeded in producing interstitial keratitis experimentally by section of the ciliary arteries, thereby affording an opportunity of examining anatomically all stages of its course, and particularly the non-malignant form, ending in recovery and mostly met with in clinical experience. As both affections, the one produced experimentally and the one known clinically as interstitial keratitis, are perfectly analogous in appearance as well as in the course they run, it is probable that the interstitial keratitis of man also is only a secondary consequence of the disease of the choroid.

Conclusions.—Here the results of experimental research are in accordance with the observations of clinical experience. The so-called interstitial keratitis is not a primary inflammation of the cornea, but one probably originating in the anterior part of the uvea, which provides the nutritive supply for the corneal tissue. It is not a characteristic symptom of hereditary syphilis, but is due to an insufficient supply of nutritive matter to the cornea, whether this is produced by cutting off the blood-supply experimentally or by diminution of the lumen of the bloodvessels through the thickening of their walls. That this latter condition (Heubner's endarteritis) is to be found in syphilitic disease of the retina and choroid, as well as in brain syphilis, has been shown by many observers. Compare, for instance, the interesting case of Dr. Barlow and Mr. Nettleship in vol. xi. of the Ophthalmic Hospital Reports. Clinically it is known that syphilis plays an important part in the production of anaemia, and perhaps in this way the surprising fact might be interpreted that boys are much less frequently the subjects of interstitial keratitis than girls (Hutchinson, amongst 102 cases, 64 females and 38 males), the great proneness of the female sex to an anæmic condition being undoubted. An interesting observation of Klebs might be mentioned in connexion with the foregoing consideration. In animals which, after inoculation with the syphilitic virus, do not develop any symptoms that could be clinically considered as parallel to the characteristic symptoms in man, frequently a state of profound anaemia is produced with a tendency to hydropic effusion.²⁷ It is most probable that the affection of the knee-joint is to be explained

in a similar way. The fact that it is the knee-joint which is most frequently affected, although not exclusively so, might be explained by its synovial membrane being the largest and by the exposed condition of the joint. I am not aware of any clinical facts which would show a similar synovitis following the arrest of blood-supply to joints by obliteration or compression of bloodvessels. To attack this question experimentally on the same lines as Wagenmann has done with regard to the ciliary vessels would be a matter of no common interest, and one which I hope to be able to approach at no distant period.

Sinclair-road, W.

RESULTS OF

MAJOR AMPUTATIONS TREATED ANTISEPTICALLY IN THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE, DURING THE YEAR 1894, AND FOR A PERIOD OF SIXTEEN YEARS AND NINE MONTHS.

By FREDERICK PAGE, M.D. EDIN., M.R.C.S. ENG.,
SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE, ETC.

DURING the year 1894 69 major amputations were performed in the Royal Infirmary upon 68 patients. In 1 case a patient lost two limbs. Sixty patients recovered and 8 died—a mortality of 11·7 per cent. Twenty-seven of the amputations were for injury, and 6 patients died—a mortality of 22·2 per cent. For disease 41 amputations were performed and 2 patients died—4·8 per cent. The following table gives the results in a tabular form:—

TABLE I.—Major Amputations treated antiseptically in the Royal Infirmary, Newcastle-upon-Tyne, during the year 1894.

	Injury.			Disease.			Total.
	No.	Recovered.	Deaths.	No.	Recovered.	Deaths.	
Double amputations ...	1	—	1	—	—	—	1

Precise Explanation of Deaths.

INJURY.

1. Man, aged forty-two years, died one hour after amputation of both thighs for crushed legs—shock.
2. Man, aged thirty-seven years, died two days after amputation of thigh for contused and lacerated leg and thigh, with wound into knee-joint—shock.
3. Man, aged twenty-four years, died a few hours after amputation of thigh for compound fracture of leg &c.—shock.
4. Man, aged thirty-seven years, died one hour after amputation of thigh for railway smash—shock.
5. Boy, aged nine years, died a few hours after amputation of thigh for compound fracture of leg—shock.
6. Man, aged fifty-six years, died seven days after amputation of thigh for compound fracture of leg of two weeks' duration—septicæmia. This patient was admitted and operated upon in a septic condition.

DISEASE.

1. Man, aged twenty-two years, died a few hours after amputation at hip-joint for advanced hip-joint disease—shock.
2. Man, aged thirty-seven years, died a few hours after amputation of the leg for ulcers, from shock.

TABLE II.—Major Amputations treated antiseptically in the Royal Infirmary, Newcastle-upon-Tyne, from Jan. 1st, 1883, to Dec. 31st, 1894, a period of twelve years.

	Injury.			Disease.			Total.
	No.	Recovered.	Deaths.	No.	Recovered.	Deaths.

Totals... ..	277	242	35	435	409	26	712

As will be seen from the above tables, during the twelve years from 1883 to 1894 712 major amputations were performed in the Royal Infirmary, and 61 patients died. This is a mortality of 8·5. The period is a long one, and every amputation performed in the infirmary during it is included. To arrive at a correct estimation of these results the nature of the amputations and the actual cause of death must be taken into account. Six patients died after double amputations and 7 recovered. Twelve patients died after amputation at the hip-joint and 17 recovered. Six of the hip amputations were primary and 3 of them proved fatal. Twenty-three were for disease and 9 ended fatally. Twenty-three patients died after amputation of the thigh and 183 recovered. Ten patients died after amputation of the leg and 136 recovered. Two patients died after amputation at the shoulder-joint and 30 recovered. Four patients died after amputation of the upper arm and 51 recovered. One patient died after amputation of the forearm and 66 recovered. Three patients died after Syme's amputation and 145 recovered.

Now I will examine the cause of death in these 61 cases, for, after all, that is the most important consideration. The causes of death were as follows:—

1. Pyæmia	9	7. Phthisis	3
2. Exhaustion	4	8. Syncope	2
3. Tetanus	4	9. Tuberculous meningitis	1
4. Recurrent gangrene ...	6	10. Delirium tremens ...	1
5. Shock and loss of blood	30		
6. Head injury	1	Total	61

It will be seen that 9 of the deaths are returned as due to pyæmia. This is 15 per cent. of the deaths, but deaths occurring some weeks after amputation, and returned as due to exhaustion, must be looked upon with considerable suspicion, and, therefore, I propose to include the 4 deaths from exhaustion amongst the deaths from septic disease. This gives 13 deaths from sepsis—21·3 per cent. of all the deaths. But there were 712 cases operated upon, 13 of which terminated fatally from some form or other of septicæmia, giving only 1·8 per cent. Tetanus, no doubt, is a form of blood poisoning, and the patients who died from recurrent gangrene would probably be septic, but I do not think I am called upon to include these. If they are to be included, then the mortality will be raised to 23, making 3·7 per cent. of all the deaths due to some form or other of blood poisoning, the mortality of the 712 amputations being, even then, only 3·2 per cent. from blood poisoning of any kind. That only 3 per cent. of the amputations in a large hospital should end fatally through any form of blood-poisoning during a period of twelve years shows a marked improvement; and, while this is so, it is significant to find how high the relative

proportion of deaths from blood poisoning remains, more than a third of the deaths being still due to some form or degree of blood poisoning.

The next important factor is shock and loss of blood, and from this cause 30 patients died—all within a few hours of operation—i.e., 49.1 per cent. of the whole number of deaths, and 4.2 per cent. of the 712 amputations. If these 30 unavoidable deaths be eliminated from the statistics, as I think they should be, then we have 682 amputations with 31 deaths, a mortality of 4.5 per cent. for the twelve years.

It is remarkable that no death is returned as having been due to secondary hæmorrhage; that formerly by no means uncommon occurrence seems to have been entirely eliminated by the antiseptic system.

With regard to the deaths from pyæmia and tetanus I am entitled to point out that 3 at least of the 9 cases of septicæmia were admitted in a septic condition, and 3 of the 4 cases of tetanus were also admitted suffering from lockjaw. No case of pyæmia after amputation has arisen since 1891 in the hospital. In that year a man, a confirmed drunkard, died seven days after amputation of his leg from pyæmia. There were no deaths from pyæmia in 1890 or in 1889. The patients who died from recurrent gangrene were all very unfavourable cases for operation. They suffered from spontaneous moist gangrene and died from that cause after amputation. That 3 out of the 9 cases of pyæmia and 3 out of the 4 cases of tetanus treated in the infirmary should have originated in private practice tends strongly to confirm the growing public opinion that patients recover much more satisfactorily after surgical operations performed in properly equipped and managed hospitals than in private houses. This conviction induces the public to prefer surgical treatment in either a public or in a private hospital, when they can get it, to treatment in their own homes, and, I am sure, the preference is a wise one. However true the conclusion Sir Jas. Y. Simpson arrived at may have been when he wrote his paper on the relative mortality after amputation in hospitals and in private practice, the position is certainly very different now. It is reversed, for there are, I am satisfied, more deaths in proportion to the number of operations from what is called "hospitalism" now in private practice than in hospitals—certainly, than in the larger public hospitals.

TABLE III.—The Number of Amputations performed from 1883 to 1894, with the Mortality of each Year.

Year.	Injury.			Disease.			Totals.	
	No.	Recoveries.	Deaths.	No.	Recoveries.	Deaths.	No.	Deaths.
1883	23	23	—	25	22	3	48	3
1884	21	19	2	36	35	1	57	3
1885	14	14	—	37	35	2	51	2
1886	25	25	—	41	37	4	66	4
1887	17	15	2	43	43	—	60	2
1888	13	7	6	29	29	—	42	6
1889	23	20	3	29	27	2	52	5
1890	35	32	3	35	33	2	70	5
1891	35	28	7	46	45	1	81	8
1892	16	13	3	30	28	2	46	5
1893	28	25	3	43	36	7	71	10
1894	27	21	6	41	39	2	68	8
Totals	277	242	35	435	409	26	712	61

The age of the oldest patient who died after amputation was seventy-seven, and of the youngest four years.

3 died aged 70 or upwards.	5 died aged 30 or upwards.
7 " 60 " "	8 " 20 " "
11 " 50 " "	14 " 10 " "
6 " 40 " "	6 died under 10 years.

I regret very much that I am not in a position to give the ages of all the patients operated upon, without which the value of the above table is much diminished.

The following table gives the results of all the major amputations performed in the Royal Infirmary, Newcastle-upon-Tyne, from April 1st, 1878, to Dec. 31st, 1894, a period of sixteen years and nine months:—

TABLE IV.—Major Amputations treated antiseptically in the Royal Infirmary, Newcastle-upon-Tyne, from April 1st, 1878, to Dec. 31st, 1894, a period of sixteen years and nine months.

	Injury.			Disease.			Total.
	No.	Recoveries.	Deaths.	No.	Recoveries.	Deaths.	
Double amputations ...	13	7	6	—	—	—	13
Hip-joint	6	3	3	25	14	11	31
Thigh	68	50	18	191	178	13	259
Knee-joint	10	9	1	6	6	—	16
Leg	96	85	11	94	91	3	190
Ankle-joint	30	29	1	138	136	2	168
Shoulder-joint	20	19	1	17	16	1	37
Arm	48	43	5	24	23	1	72
Forearm	44	43	1	35	35	—	79
Wrist	7	7	—	—	—	—	7
Totals	342	295	47	530	499	31	872

Thus there were 872 amputations, with 78 deaths—a mortality of 8.9 per cent.; 342 of the amputations were for injury, and 47 patients died—13.7 per cent.; 530 of the amputations were for disease, and 31 patients died—5.8 per cent.

From a paper published by Dr. Sam. Fenwick in the year 1848 on the surgical operations performed in the Newcastle-upon-Tyne Infirmary during a period of seventeen years and six months I have taken the following table showing the results of major amputations:—

TABLE V.—Major Amputations treated in the Infirmary, Newcastle-upon-Tyne, during a period of seventeen years and six months.

	Injury.			Disease.			Total.
	No.	Recoveries.	Deaths.	No.	Recoveries.	Deaths.	
Thigh and knee	8	3	5	50	41	9	58
Leg and ankle	38	24	14	74	59	15	112
Shoulder-joint	5	3	2	—	—	—	5
Arm and elbow	24	20	4	11	10	1	35
Forearm and wrist	6	5	1	9	6	3	15
Totals	81	55	26	144	116	28	225

Two hundred and twenty-five patients were operated upon during that period, and 54 died—just 24 per cent. Eighty-one of the amputations were for injury, 3 being double amputations, and 26 patients died—32 per cent. One hundred and forty-four were for disease, and 28 patients died—12.5 per cent. It is interesting to compare these results with those extending over a very similar period some forty years later. The tables indicate to what an extent the work of the institution has increased and how strikingly the mortality has decreased. The precise causes of death are not given by Dr. Fenwick, but there is evidence that a large proportion of the deaths, as would be expected, arose from pyæmia.

Newcastle-upon-Tyne.

GALASHIELS COTTAGE HOSPITAL.—The first annual meeting of the managers of this hospital was held on March 29th in the Burgh Buildings, Galashiels, Mr. Brown (ex-provost) presiding. The report stated that from the opening of the hospital in November, 1893, to the end of December, 1894, there had been fifty-one patients admitted, of whom two died. The income during the same period was £654 and fell short of the expenditure by about £20. The cost of building and furnishing the hospital was £4482. The grounds extend to an acre and a half, picturesquely situated by the river Tweed.

CASE OF ADDISON'S DISEASE; NECROPSY.

By C. CRAWFORD AITKEN, M.B. EDIN.

ON Nov. 23th, 1894, I was called to see a farm labourer aged fifty-nine years. He complained of weakness, nausea and vomiting, and had been ill for about nine months. His previous health had been very good, and with the exception of a dislocation of the shoulder-joint, sustained through a severe fall five years before, he had never had any serious accident. He gave a satisfactory family history, but two brothers appear to have died from phthisis. His habits as to food and drink were good; his home was comfortable; and his work, though exposing him occasionally to the inclemencies of the weather, was light and wholesome. His original occupation was that of a butcher, but in 1889 he had been obliged to resign it and turn for a livelihood to farm labour. The illness of which he complained commenced insidiously. The initial symptoms were languor, depression of spirits, and fatigue after exertion, and were first noticed in the previous February. They became gradually more pronounced, and were supplemented in April by attacks of headache, giddiness, palpitation, and shortness of breath. His appetite, moreover, became exceedingly poor, and he began to experience vague pains, shooting and burning in character, in the region of the stomach. He consulted a medical man and was told that he suffered from indigestion. He accordingly had a course of medicinal treatment; but his condition, instead of improving, grew daily worse, and the weakness became at length most distressing. He continued, however, his employment, and throughout July worked hard at the hay harvest. But the severe manual labour and the heat of summer told so disastrously upon his already enfeebled frame that eventually, in the second week of August, he was obliged to give up work and take to bed. His friends noticed that he was looking worn and ill, and that his face and hands had a peculiar yellowish discolouration. He placed himself a second time under treatment, but his condition showed not the least amelioration. He began in September to suffer frequently from nausea and vomiting. The nausea, though usually worst in the morning, persisted often for an entire day, and prevented him taking a due amount of nourishment; while the vomiting attacks, accompanied as they were by intense retching, left him on each occasion sensibly weaker, and reduced him at last to a condition of extreme prostration. His throat was very sore after the vomiting, and occasionally his sputum would be blood-streaked. He had, moreover, developed latterly a slight cough and become emaciated; but had no diarrhoea, night-sweating, or hæmoptysis. When I saw him on Nov. 23th he was utterly exhausted with the recent and severe vomiting. Although of powerful build and muscular development, he was markedly emaciated, and one could not fail to be struck with the peculiar cachectic appearance he presented. The cheeks were hollow, the eyes sunken, the lips somewhat cyanosed; the ocular conjunctivæ were yellowish and slightly injected, while the skin had a distinctly sallow tinge, which on exposed parts, in the flexures of joints, and in the region of the genitals deepened gradually, though decidedly, into shades of walnut-brown, the hands, axillæ, genitals, and back of the neck being the regions most pigmented, while the scalp, front of the chest, abdomen, legs feet, and mucous membrane of the mouth were apparently unaffected. The discolouration varied much in its intensity in different parts, but was of uniform type and uninterrupted by spots or mottling of any kind. The skin was free from eruption, excess of moisture, and itching; and there was, with the exception of blueness of the lips and faint duskeness and clubbing at the finger-tips, no cyanosis and no oedema. There were no evidences of acute suffering, but the whole attitude and expression of the patient betokened great mental depression and physical exhaustion. He lay in a listless, semi-comatose state, sighing and yawning frequently. He had no appetite, and complained much of thirst, heartburn, flatulence, and pyrosis, with dull aching pain in the epigastrium and feelings of distension and weight about the stomach. He had, moreover, been very sick all the morning, and had vomited all his food a few minutes after taking it, each ejection being accompanied and preceded by intense stomacheic pain and retching. Examination of the abdomen threw no light upon the causation of such symptoms. There was, indeed, some tenderness on pressure in the epigastric

and hypochondric regions; but no tumour was anywhere discoverable, and the liver and stomach were not enlarged. The bowels were sluggish and the faecal matter small in amount and pale almost to chalkiness; but neither that nor the vomited matter contained any blood, and the patient did not suffer from hæmorrhoids. There was, however, considerable anaemia. It was unaccompanied by any enlargement of blood glands and was evidently not due to hæmorrhage. The symptoms were headache, giddiness, buzzing in the ears, palpitation, and shortness of breath on exertion. There was a loud hum in the external jugular vein and a systolic murmur in the cardiac pulmonary area. The heart was apparently free from valvular lesion; but the heart sounds, especially the first, were extremely faint. The pulse was regular, moderate in frequency, small in volume, and of low tension. The temperature was subnormal. The urine was clear and straw-coloured, and showed no traces of sugar, albumen, bile, or blood pigments. The patient had a slight cough, with expectoration of scanty, frothy, blood-streaked mucus. The breathing was shallow and the breath sounds almost inaudible. Crepitations, non-consonating, were audible at the base of each lung, and all over the chest were faint rhonchi, while at the right apex there were a few fine crepitations and a slight prolongation of expiration. There was, however, no dulness or other sign of consolidation. After a careful consideration of the symptoms of the case as a whole, and of the possibility respectively of malignant disease, gastric ulcer, biliary obstruction, chronic phthisis, Bright's disease, and pernicious anaemia, the provisional diagnosis of Addison's disease was made. The prognosis was hopeless, and the treatment, which consisted of milk diet, stimulants, and arsenic, was useless. The patient lingered on for three days, semi-comatose and almost pulseless, and died on the evening of Dec. 1st.

Necropsy on Dec. 4th, 1894.—Putrefaction was just beginning to show itself in green discolouration of the abdomen. Rigidity was present in all the muscles and hypostasis was well marked. The pigmentary changes in the skin of various regions were distinct, more so perhaps than in life. The muscles were much wasted, but there was a fair amount of subcutaneous fat. The heart, which was the first organ examined, was small, pale, and uncontracted, rough and lymph-coated on its epicardiac surface, but inside quite free from endocardiac or valvular disease. The lungs were crepitant throughout and had no morbid excavation or consolidation; but the lower lobes of each lung and the apex of the right were profoundly congested. The stomach was of normal size and contained a little milky food. Its mucous lining was pale, covered with glairy mucus, ecchymosed, and slightly mammillated at the pylorus, but without any signs of ulceration or cicatrices. The intestine, beyond slight congestion of its Peyerian patches and prominence of the solitary follicles, showed nothing abnormal. The spleen was small and shrivelled, and its pulp in a liquid condition; but the liver, gall-bladder, and bile-ducts, with the kidneys and the pancreas, were apparently normal. The adrenals both showed remarkable changes. The right one was, in its lower part, quite hard and calcareous, while the left was represented by a caseous, nodulated, cubical mass two and a half inches in diameter, which on section showed rounded cheesy areas of a yellow colour, separated from one another by bands of darker-coloured fibrous tissue. Each supra-renal mass was perfectly circumscribed, but surrounded by a considerable amount of thickened connective tissue, in which many of the nerve fibres connected with the solar plexus were implicated. No change, however, was observed in the surrounding ganglia or in neighbouring lymph glands.

Barnsley.

A CASE OF RUPTURE OF THE UTERUS OCCURRING AT THE FIRST ONSET OF LABOUR.

By WM. HARRIS BEST, L.S.A. LOND.

As rupture of the uterus early in labour is of very rare occurrence, I think the following case should be recorded.

The patient, aged thirty-two, mother of seven children, of good physique and accustomed to work hard in household matters, but always having plenty of good nourishment, was attended in her previous confinement by myself, about

eighteen months before the present one. She never had any miscarriage or other symptom of syphilis. I find the following note in my case-book relating to her last confinement: "Long and tedious first and second stages; pelvis roomy; presentation first cranial. Ergot was of decided benefit in arousing uterus to stronger action during second stage. On the fifth day I found on visiting my patient that she was dressed and downstairs, so I immediately ordered her back to bed, where she remained until the tenth day. No ill effects apparently followed this early rising beyond slight increase of discharge. This, her eighth, confinement commenced in the following unusual manner. She and her husband went to bed as usual about 11 P.M., she feeling perfectly well at the time. Very shortly after they had been in bed she said to her husband, 'I believe my confinement is coming on.' A few minutes after that she said, 'I am sure it is so; you had better get up at once.' After he had got up she hurried him off, saying it was coming on quickly. As I was not at home when the message arrived my assistant went immediately. On his arrival he found the nurse there, and was told by her that shortly after the husband had left a smart hæmorrhage had occurred from the vagina; there was ample evidence of this in the condition of the bedclothes near the patient. But one pain occurred and was followed by a gush which she thought was the liquor amnii following the sudden rupture of the membranes. The hæmorrhage ceased when the nurse changed her from the right to the left side; continuous pain was from this time felt on the left side of the abdomen. After waiting about three-quarters of an hour, as labour pains did not come on, I was sent for. On my arrival I found the patient had rather an anxious look on her face. The left-sided pain, though not severe, became so if the abdomen was handled or if she was moved or attempted to move herself. She appeared very nervous and upset, so that it was difficult to tell definitely whether the pain was very acute or the tenderness very great, as she cried out as soon as the vulva was touched in making a vaginal examination. There was practically no collapse, and the depression was only such as might have been produced by a slight hæmorrhage. Her pulse was fairly good, 80 beats to the minute. The patient appeared very much disturbed at the prospect of being touched or examined. The pain was confined to the left side and was not severe, the patient talking in an ordinary way and not complaining unless she attempted to move. On vaginal examination I at first failed to reach the presenting part or, indeed, the os; on inserting the whole hand into the vagina, however, I could get my middle finger inside the os only about one-third of an inch, but felt nothing definite. Though the patient said she had felt movements of the child shortly before labour I could not hear the foetal heart sounds. Abdominal palpation yielded no definite result as the patient could not bear its being done properly. Nothing definite was thus made out by either examination. The patient now begged to be left alone for a time, and as her pulse remained fairly good and there was but little pain we did so. Neither labour pains nor hæmorrhage occurred for the next hour; her pulse remained about the same, and she became rather more comfortable. At this stage the case looked like either a placenta prævia or slight accidental hæmorrhage, the pulse keeping good, and the patient not complaining of feeling faint or exhausted appeared to place concealed hæmorrhage or ruptured uterus out of the question. As at this time the patient's condition appeared to be improving rather than going back I decided not to use any means for bringing on labour, at least for a time, other than plugging the vagina and orifice of the womb, which latter would answer the double purpose of preventing further external hæmorrhage and keep up a slight reflex stimulation on the womb. This was carefully done with iodoform wool pellets. A few hours after this the patient did not appear to have altered much. She took nourishment and kept it down; her pulse was, however, quicker, her face looked more anxious, and a feeling of sickness was complained of. Her temperature in the mouth was 101° F. I now decided to endeavour to accelerate labour by resorting to more active measures. No hæmorrhage followed the removal of the plugging. On

making a vaginal examination a hard indistinctly fluctuating mass was found in front of the anterior vaginal wall and remained after the bladder was emptied. A Barnes' bag was with difficulty passed through the os, the difficulty not arising from the rigidity of the os or any malposition of it, but from its great height. Ergot was given by the mouth freely. No real labour pains followed, though about an hour afterwards the bag was found in the vagina and the os readily admitted two fingers. Still no presenting part could be definitely made out. The next size Barnes' bag was easily passed, and after a time, on its removal, three fingers could easily be passed through the os, and a shoulder was found presenting. Without much difficulty, by means of the bipolar method of version, a foot was brought down into the lowest and posterior part of the uterus. The child was found to be dead, skin peeling off the foot. The passive condition of the uterus during removal of the child was noticeable. No blood or liquor amnii up to this time had escaped. A rupture in the anterior uterine wall could now be detected. The placenta, which was found to be quite free in the uterus, was easily brought away, the uterus remaining flaccid. Hypodermic injections of ether and ergotin were now given, as the patient complained of feeling faint. She quickly revived. The uterus could not be made to contract, though not even an ordinary amount of external hæmorrhage occurred. An iodoform and eucalyptus suppository was left in the upper part of the vagina with its apex passing through the external os, and repeated every six hours. Sickness gradually increased, and the patient died thirty-six hours after the birth of the child with symptoms of peritonitis and exhaustion. No post-mortem examination could be obtained."

The points worthy of particular notice in this case appear to be (1) the very early stage at which rupture occurred; (2) the absence of any other exciting cause than the faulty position of the child (no marked anteversion of the uterus being made out); and (3) the comparative mildness of the first symptoms occurring after so grave an accident.

Ilford, Essex.

NOTE ON THE RELATION BETWEEN DYSENTERY AND LIVER ABSCESS.

BY A. W. D. LEAHY, M.D. DURH., F.R.C.S. ENG.,
SURGEON-MAJOR, INDIAN MEDICAL SERVICE.

SOME observers have of late gone the length of denying that any connexion exists between dysentery and abscess of the liver. It is possible, therefore, that notes of the following case may prove of interest to the profession, for I think it demonstrates the connexion which existed between an attack of subacute dysentery and the subsequent formation of an abscess in the right lobe of the liver.

A European male, aged twenty-nine years, was attacked by dysentery on June 18th, 1894. The actual dysenteric attack was comparatively slight in character, confining him to his

bed for five days only; but after the disappearance of the more urgent symptoms he continued to suffer from diarrhoea until the end of July. He was under the treatment of Dr. J. F. P. McConnell and was quite well by July 23rd. On the last day of August, 1894, he began to suffer from fever, his temperature going up to 102° F. in the evening and falling to 99° 6' in the morning. To get rid of this fever he went to Darjeeling on Sept. 8th, and returned

thence to Calcutta on Oct. 1st free from fever. The patient consulted me on Oct. 26th for a recurrence of the fever, and, though I carefully examined his liver on that day, there were no physical signs of anything being amiss with the organ. I saw no more of him until Nov. 29th last, when he sent for me, and I found him in bed suffering from great pain in, and with some tenderness of, the hepatic region. His temperature showed a daily rise of from two to three degrees, and never reached the normal limit in the morning. The symptoms during the earlier days of his illness were somewhat masked, but their obscurity gradually cleared up, and on Dec. 12th distinct enlargement with slight bulging of the liver was made out just below the right costal arch. On Dec. 16th this swelling was aspirated and ten ounces of typical hepatic pus were withdrawn. This pus was immediately examined under the microscope by Professor D. D. Cunningham, and was found to contain amœbæ coli in abundance. Four days later the abscess was freely opened and a large drainage-tube inserted. The patient made rapid strides towards recovery, and at the date of writing this the wound in the liver has healed and he is able to take carriage exercise daily. As regards the rapid cure it is needless to say anything, for it is an ordinary successful case of liver abscess treated by free incision and drainage, without washing out the sac with any of the numerous antiseptic solutions. The interest of the case appears to me to lie in the following. A young man, hitherto perfectly well, is attacked by dysentery in the month of June. The dysenteric attack lasts until the latter part of July. In the month of November, after an interval of four months, more or less pyrexial in character, he develops distinct symptoms and physical signs of an abscess in the right lobe of the liver. This abscess is aspirated under precautions that prevent the admission of any air, and the pus thus obtained is immediately subjected to examination under the microscope and found to contain the amœbæ of dysentery. It is known that in cases of dysentery these amœbæ coli are present in the stools and in the walls of the gut which are undergoing dysenteric ulceration. It is also known that one property possessed by these organisms is motility and the power of transporting themselves. May it not then be assumed, looking at this case, that the organisms found in the pus from the liver abscess have had their origin in the previous dysenteric process and have travelled from the ulcerated gut to the liver? Their presence in the liver in this case was a *fact*, and the observation of this one fact is worth many theories. Kartulis, Councilman, and Lafleur have all observed the presence of these amœbæ in cases of abscess of the liver. How the amœbæ get to the liver from the diseased gut must at present be largely a subject for speculation. Do they travel up through clots which block the lumen of vessels opened up by the ulcerative process of dysentery? Or do they reach the liver by way of the lymphatic system? We also know but little as to the part played by them in causing the abscess. They are comparatively large motile bodies, and it cannot be said whether they, by their presence, cause the breaking down of the liver substance, or whether they only act as carriers of some septic poison, which by its irritant properties gives rise to the abscess.

The practical value of the case I have recorded rests, I think, upon three points—viz., (1) the known date of the previous attack of dysentery; (2) the subsequent formation of the abscess in the liver with the pyrexial interval; and (3) the presence in the pus from the abscess of the amœbæ of dysentery. These three points are so closely connected that I think it may safely be affirmed that so-called single tropical abscess of the liver does in some cases owe its existence to a previous attack of dysentery and is due to the amœbæ finding their way from the diseased part to the liver.

Annexed is a chart showing the patient's temperature during the progress of the case.

Calcutta.

FOREIGN UNIVERSITY INTELLIGENCE.—Vienna: Professor Max Gruber, who is already on the Council of Hygiene, has been elected a member of the municipality. Dr. Max Salzmann has been recognised as a *privat-docent* in Ophthalmology. Prague: Professor Wilhelm Czermak has been appointed to the chair of Ophthalmology in succession to Professor Schnabel.

OF

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

THE series of cases of diphtheria treated by antitoxin which appear in the subjoined reports form a valuable contribution to the subject, and confirm the opinion that the remedy is one of considerable efficacy. The cases, being all treated in hospital and the diagnosis in each controlled by the bacteriological test, were observed under conditions favourable to the formation of a just appreciation of their character and of the influence of antitoxin upon them. We would draw particular attention to the fact that no less a proportion of the cases reported from University College Hospital than six out of thirteen necessitated tracheotomy, and that of these tracheotomised subjects only one succumbed. Another fact of interest is that of death from suppression of urine after seven weeks' illness in a case of pharyngeal diphtheria, and a clue to this exceptional course is probably afforded by the fact that one of the kidneys was atrophied and cystic. It might be also suggested that the defective renal elimination in this case had some relation to the roseolous rash which appeared on the skin during treatment. In his remarks on these cases it will be seen that Mr. Bunch notes that a rash appeared in three cases, in each case accompanied by a rise in temperature. His suggestion as to the possibility of the fluid containing some impurity is one deserving of the most careful scrutiny. We publish in another column (p. 949) the judgments of several well-known German physicians, and the motion adopted by the Congress of Internal Medicine, meeting now at Munich, on the subject.

UNIVERSITY COLLEGE HOSPITAL.

THIRTEEN CASES OF DIPHTHERIA TREATED WITH ANTITOXIN; REMARKS.

(Under the care of Dr. FREDERICK ROBERTS.)

EVIDENCE as to the value of antitoxin in the treatment of diphtheria is being accumulated, and there is no doubt that this remedy has proved successful in many cases. At the recent discussion at the Royal Medical Society of Vienna, Dr. Monti, Dr. Hein, and Dr. Unterholzner gave statistics of eighty-three cases which had been treated by them, with a mortality of only 18.07 per cent. Dr. Kolisko at the same meeting reported that from post-mortem examination of fatal cases in which the serum had been used he had found the membrane much less firmly attached to the mucous membrane than in the fatal cases treated by other methods. Many of the accounts of patients who have died show that they were treated at a late stage; in fact, when almost dying—at a period, in fact, when no improvement could be expected from any treatment. The following thirteen cases of diphtheria were taken into University College Hospital during the months of December and January last, and were all injected with antitoxin within a short time of admission. Of these cases two were fatal—one on the third day through broncho-pneumonia, and the other through suppression of urine after seven weeks' illness. During the same period another case of diphtheria was admitted, but in a moribund condition, the child dying before antitoxin could be injected. Six cases out of the thirteen had tracheotomy performed, and of these one was fatal, the other fatal case being one of pharyngeal diphtheria in which the larynx was not affected. The antitoxin injected was in every case that obtained from the British Institute of Preventive Medicine. The bacteriological examinations were made by Dr. H. R. Smith, Dr. Paul, and Mr. Watts. For the

notes of these cases we are indebted to Mr. J. L. Bunch, house physician.

CASE 1. Tracheotomy; rash; recovery.—The patient, a boy aged nine years, was admitted on Dec. 1st, 1894, with dyspnoea and recession, but with no membrane visible in the throat, this being apparently the second day of the illness. Tracheotomy was performed, and 20 c.c. of antitoxin were injected into the lumbar region. On the 2nd the dyspnoea was relieved, but still no membrane could be seen. On the 4th a rubber tube was substituted. On the 16th the temperature rose to 103.2° F.; the child complained of acute pains in the limbs; and a papular eruption appeared on the limbs, trunk, and face. The glands at the angle of the jaw were enlarged, but no joints were swollen. On the 18th the rash had disappeared, and the pain in the limbs diminished, but the breathing became laboured, and a tube had to be inserted again through the tracheotomy wound. On Jan. 7th, 1895, the temperature rose suddenly to 104°, and some fluid was detected in the left knee-joint. The patient was discharged on Jan. 10th without paralysis. No albumen was present at any time, but typical bacilli were found in cultivations from the trachea.

CASE 2. Tracheotomy; recovery.—The patient, a girl aged nine years, was admitted on Dec. 8th, 1894, with membrane on both tonsils and on the uvula, this being the third day of illness. Twenty c.c. of antitoxin were injected. On the 9th the membrane had spread to the trachea, and the temperature was 103.6° F. Tracheotomy was performed, and another 10 c.c. of antitoxin were injected. On the 10th the membrane was less, the maximum temperature being 102.2°. A trace of albumen was now present in the urine. On the 11th the membrane was diminished in extent and patchy; the temperature was 101°. On the 16th the membrane disappeared, but there was one-fourth albumen. The temperature was 100°. The patient progressed but slowly and was kept in hospital until Feb. 8th, 1895, her knee-jerks not having returned. On admission diphtheritic bacilli were found in cultivations, but in another cultivation made on Feb. 7th only streptococci, staphylococci, and diplococci were present.

CASE 3. Tracheotomy; erythematous rash; recovery.—The patient, aged five years, was admitted on Dec. 19th, 1894, with membrane on both tonsils and stridulous breathing. Twenty c.c. of antitoxin were immediately injected, and tracheotomy was performed later in the day. On the 20th the child was breathing quietly, and the temperature had fallen from 102° to 100.6° F. On the 21st no membrane was present in the throat, but the tonsils were raw and bleeding. On the 27th an erythematous rash appeared on the forearms and chest, but there were no pains in the limbs. On Jan. 2nd, 1895, a diffuse rash came out all over the body, accompanied by a slight rise of temperature. On the 4th the rash had disappeared. The patient was discharged on Jan. 12th quite well. Cultivations showed typical bacilli. A slight trace of albumen was present.

CASE 4. Pharyngeal diphtheria; recovery.—The patient, aged six years, was admitted on Dec. 17th, 1894, on the third day of illness, with membrane on both the tonsils and soft palate. Twenty c.c. of antitoxin were injected. On the 18th the membrane had not diminished, and another 10 c.c. of antitoxin were injected. Some albumen was present. The temperature was 102° F. The membrane decreased slowly until the 27th, when it disappeared. The patient was discharged on Jan. 7th, 1895, without any paralysis, but a faint cloud of albumen. Cultivations showed diphtheritic bacilli.

CASE 5. Nasal and pharyngeal diphtheria; recovery.—The patient, aged two and a half years, was admitted on Dec. 20th, 1894, after two days' illness. Membrane was present on both tonsils, and there was a discharge from the nose. Twenty c.c. of antitoxin were injected. On the 21st the nasal douche brought away casts of the turbinate bones. Membrane was still present on the 23rd, and another 5 c.c. of antitoxin were injected. This was followed by disappearance of the membrane on the 24th, and of the swelling around the angle of the jaw. The patient was discharged on Jan. 5th, 1895, quite well, but a cultivation was made from his throat on Feb. 18th. This showed a complete absence of the diphtheritic bacilli, which were abundantly present on admission.

CASE 6. Pharyngeal diphtheria; erythematous rash; suppression of urine; death after seven weeks.—The patient, a girl aged four and a half years, was admitted on Dec. 23rd, 1894, after two days' illness. She was the sister of the last-mentioned patient. She had membrane on both tonsils and on the soft palate; the temperature was 103.2° F., but there was no albumen in the urine; 20 c.c. of antitoxin were

injected during the course of the day. Cultivations from the throat showed numerous bacilli diphtheria. On the 24th there was still a good deal of membrane, but the highest temperature was 101.6°. On the 28th membrane was still present, and nasal douches brought away a large piece of membrane. There was one-eighth albumen. On Jan. 1st, 1895, a diffuse red rash came out over the body, and the temperature rose in the evening to 102°. There were no pains in the limbs. There was one-fifth albumen in the urine. On the 8th no membrane was to be seen. The urine seemed scanty, and when measured was found to be only six ounces during the previous twenty-four hours. There was one-fifth albumen in the urine. The latter was secreted only in small amount from now until the patient's death, not exceeding twelve ounces in any one twenty-four hour period. The albumen gradually decreased, and by Jan. 23rd had entirely disappeared. The child seemed to be fairly well in herself, but was kept in bed, as no knee-jerks were obtainable and the palate moved badly. On Feb. 6th she had an attack of dyspnoea and became cyanosed, having passed only three ounces of urine during the previous twenty-four hours. There was now so much difficulty in swallowing that she had to be fed with a nasal tube. On the 8th, while being fed with the nasal tube, she died suddenly. The amount of urine passed in twenty-four hours for the last few days of life was as follows: Jan. 29th, 9 oz.; 30th, 10 oz.; Feb. 1st, 8 oz.; 2nd, 7 oz.; 4th, 5 oz.; 5th, 6 oz.; 6th, 3 oz.; and 7th, 6 oz. At the necropsy Dr. Poore found the right kidney to be large and congested, weighing three ounces; the left kidney was small, cystic, and weighed only half an ounce. Dr. Sidney Martin found degeneration of all the peripheral nerves examined, both sensory and motor.

CASE 7. Tracheotomy; broncho-pneumonia; death.—The patient, aged one year and a half, was admitted on Dec. 21st, 1894, with considerable recession, being obviously very ill. This was stated to be the fourth day of illness. Tracheotomy was performed. On the next day there was no change for the better, and 20 c.c. of antitoxin were injected. On the 23rd the child was cyanosed, breathing rapidly and shallowly, and rales were heard all over the chest. Another 5 c.c. of antitoxin were injected, but the patient never rallied and died the same morning. At the necropsy membrane was found to have extended into the second bronchial ramifications, and broncho-pneumonia was present. Cultivations showed numerous bacilli.

CASE 8. Pharyngeal diphtheria; recovery.—The patient, aged six and a half years, was admitted on Jan. 2nd, 1895, with membrane on both tonsils and on the soft palate, and one-third albumen in the urine; 10 c.c. of antitoxin were injected. The membrane was less next day, and so was the albumen, and on Jan. 4th no membrane was to be seen. On Feb. 16th the knee-jerks were still absent. Typical bacilli were found in cultivations.

CASE 9. Pharyngeal diphtheria; recovery.—The patient, aged thirty years, was admitted on Dec. 30th, 1894, after three days' illness, with membrane on both tonsils and on the uvula. Fifteen c.c. of antitoxin were injected. The membrane gradually diminished and had disappeared by Jan. 2nd, 1895. No paralysis supervened.

CASE 10. Tracheotomy; recovery.—The patient, aged one year and a half, was admitted on Jan. 15th, 1895, with considerable recession, but no visible membrane. Tracheotomy was performed, and 15 c.c. of antitoxin were injected. On the 16th the temperature was 104° F., but the breathing was much relieved. On the 17th the temperature fell to 100.4°; some amount of bronchitis was present. Improvement was uninterrupted until Feb. 4th, when the patient was discharged. No albumen was detected at any time, and no paralysis supervened. Numerous typical bacilli were found.

CASE 11. Pharyngeal diphtheria; recovery.—The patient, a man aged twenty years, was admitted on Jan. 23rd, 1895, with membrane on one tonsil and on the uvula, and a trace of albumen in the urine; 18 c.c. of antitoxin were injected into the subcutaneous tissue of the abdominal wall. On the 24th the membrane was more patchy, less in amount, and less firmly adherent to the tonsils. The tonsils were, however, swollen, inflamed, and in places appeared to be ulcerated. The patient seemed to be pretty well in himself, though rather pale and anæmic. On the 26th no membrane was to be seen. He was discharged on Feb. 4th without any paralysis or other sequelæ. Cultivations on blood serum showed colonies of diphtheritic bacilli and some cocci.

CASE 12. Tracheotomy; some paralysis when discharged.—The patient, aged two and a half years, was admitted on

Jan. 6th, 1895, after a week's illness, with membrane on both tonsils and in the trachea. Tracheotomy was immediately performed, and 10 c.c. of antitoxin were injected. The temperature rose to 102.4° F. during the night, but there was less membrane to be seen next day. The urine contained one-half albumen; 8 c.c. of antitoxin were again injected. On the 9th another 5 c.c. of antitoxin were injected, the temperature being 101.6°. The membrane gradually diminished and finally disappeared by the 11th; there was now only a trace of albumen. Considerable difficulty was experienced in trying to do without the tracheotomy tube, and it could not be left out altogether until the 22nd. The patient was discharged on Feb. 8th with weakness of the right side and the knee-jerks absent, but was readmitted on the 13th under the care of Dr. Poore with lobar pneumonia. Numerous bacilli were found soon after his admission.

CASE 13. Pharyngeal diphtheria; slight paralysis.—The patient, aged ten years, was admitted on Jan. 29th, 1895, with membrane on both tonsils and on the uvula, and a trace of albumen in the urine, having been ill three days; 10 c.c. of antitoxin were injected, and again 10 c.c. next day (the 30th). The throat cleared up gradually, and by Feb. 4th no membrane could be seen. The knee-jerks were absent from an early stage of the illness, and were still absent on March 1st. Diphtheritic bacilli were found in cultivations.

Remarks by Mr. BUNCH.—The percentage of deaths (15.4) in this series of cases is considerably below the average of deaths from diphtheria, and even of those cases previously treated with antitoxin in University College Hospital. The number of cases is, of course, too small to afford statistics of value, but it may certainly be said that the cases were at least of average severity. The antitoxin previously used in University College Hospital was obtained from a different source to the Institute of Preventive Medicine, but the objection urged against the latter that the injections are rather bulky was found in practice to be of little weight, for the swelling soon subsided, and in no case was inflammation set up around the point of injection. There was, however, some amount of tenderness, varying with the age of the patient. The three cases in which a rash appeared after the injection of antitoxin are of interest, for in every case the eruption was accompanied by a rise of temperature, and in one case by rather severe pains in the limbs, causing the child to cry out with pain. In this case the rash appeared fifteen days after injection, and presented an appearance markedly resembling that of röheln. In another case the rash came out nine days after injection, and was more of an erythematous character. In another child a rash appeared twice with an interval of six days, the first time eight days after injection. It seems possible that some impurity or septic material was contained in the fluid injected, for the strictest antiseptic precautions were taken to sterilise the syringe and needle, and disinfect the skin. Two of the cases which thus developed a rash progressed very slowly, and one eventually died from suppression of urine. Though the total number of deaths was so small, it could not be said that the membrane disappeared immediately after antitoxin had been injected, or even that the albumen always diminished, for in one case membrane was seen fifteen days after the first injection, and albumen appeared in the urine a few days after the injection, though none was present on admission. One of the children on whom tracheotomy was performed was only one and a half years old, but she stood the operation well, and recovered rapidly.

BROMLEY AND BECKENHAM FEVER HOSPITAL.

THREE CASES OF DIPHTHERIA TREATED WITH ANTITOXIN SERUM; TRACHEOTOMY PERFORMED IN TWO OF THE CASES; RECOVERY IN ALL.

(Under the care of Dr. G. W. DAVIS and Mr. R. A. SHANNON.)

WE are hearing much more hopeful accounts of the results of tracheotomy and intubation in diphtheria under the antitoxin treatment in our large hospitals than was the case a few months ago, but we cannot at present furnish statistics on this point. The communication to the Société Médicale des Hôpitaux of MM. Lebraton and Magdelaine, besides furnishing evidence of the general value of the remedy when used by them at the Hôpital des Enfants Malades, gives also some account of the results obtained when it was necessary to perform one of these operations. Two hundred and fifty cases were treated by

the antitoxin treatment in a period of three months, with a mortality of 9.2 per cent. After tracheotomy (the cases requiring it are always serious) there was a mortality of 37.5 per cent. After intubation the mortality was 15.9 per cent. when those dying within twenty-four hours after admission from lung complications or general intoxication were deducted. The three cases here reported were all of them affected with undoubted diphtheria, proved by bacteriological investigation in one of the cases, and clinically evident in the other two. Mr. Shannon and Dr. Davis believed that not one of the cases would have recovered but for the use of antitoxin.

CASE 1.—A male child, eighteen months old, was first seen at midday on Oct. 17th, 1894. The infant was suffering from diphtheritic sloughs on both tonsils, croupy cough, and inspiratory retraction of the intercostal spaces and ensiform cartilage; the temperature was 102° F. (The Clinical Research Association confirmed the diagnosis by telegram on the 18th: "Many Klebs-Löffler bacilli.") At 12.30 P.M. seven minims of Aronson's antitoxin were injected into the left forearm. At 4 P.M. the arm was swollen and red. The cough was very croupy in character; the child refused all food. There was marked retraction of the supra-clavicular and infra-clavicular area in inspiration. At 10 P.M. the retraction was more marked. There was retraction of the entire sternum in forced inspiration. A second fifteen minims of antitoxin were injected into the right forearm. On the 18th, assisted by the parish nurse, Dr. Davis administered chloroform and performed tracheotomy at 1 A.M. At 10 A.M. the child breathed easily. The tube was cleaned every two hours. At about 6 A.M. the patient became very collapsed, but rallied. At 12 (midday) there was abundant membrane in the tube: one pint of milk had been taken since the operation. On account of the offensive character of the stools three grains of calomel was ordered. At 4 P.M. the tube, nearly choked with membrane, was difficult to clear. The child took milk well. The wound was becoming sloughy. At 8 P.M. he was pale and ceased to care for his milk; the membrane was increasing in quantity, and the temperature was 100.8°. A third fifteen minims of antitoxin were injected into the left forearm. On the 19th sixteen ounces of milk had been taken during the night. From this time the child passed from Dr. Davis's care to that of Mr. R. A. Shannon of the Bromley and Beckenham Joint Fever Hospital. On the 28th it was necessary to clean the cannula every two hours night and day; the whole tube was removed every day, but great embarrassment and lividity occurred, so that it had to be replaced. The membrane from the cannula was sent to the Clinical Research Association, and the following report was received: "No bacillus diphtheriae; numerous streptococci and staphylococci." On the 30th a soft rubber tube was substituted for the silver one. A drop or two of a solution of menthol in olive oil (two grains to the ounce) was introduced into the tube every half hour, after the suggestion of Dr. Roux. Very severe coughing followed upon the introduction of the rubber tube. At 4 A.M. on Nov. 2nd the matron was urgently called by the night nurse, and found the child apparently dead and cold. The tube had been coughed out, one of the eyelet holes for the tape having split. With commendable presence of mind she replaced the tube and performed artificial respiration, and had the satisfaction of seeing the child revive. The tube was held in place until another could be obtained. On the 8th a fenestrated rubber tube was substituted. On the 17th the child was quite well, but it was found impossible to do without the tube. The child was discharged wearing the tube, in the hope that after remaining some days at home he might be removed to a general hospital. The air of a poor and crowded home set up symptoms which threatened septic pneumonia, so that on Nov. 21st Dr. Davis sent him to St. Thomas's Hospital, asking if he could be admitted and an endeavour made to wean him of the tube; this was done, and he was discharged cured on Jan. 11th without the tube. Whilst at St. Thomas's Hospital a second tracheotomy was performed below the first, and the trachea above dilated.

CASE 2.—On Nov. 13th, 1894, a girl four years of age was admitted into the Bromley and Beckenham Fever Hospital with severe diphtheritic involvement of the fauces and tonsils, the glands about the angle of the jaw were involved on either side, and the involvement of the trachea was marked with loss of voice and a very bad croupy cough, associated with marked inspiratory retraction. On the 15th the case was one of extreme gravity; the child was voiceless, with a dull,

opaque, bluish-white complexion, was unable to take any nourishment, and from time to time vomited; there were also attacks from time to time of such severe dyspnoea that the case looked extremely hopeless. Under these circumstances Messrs. Shannon and Yolland, medical officers of the hospital, invited Dr. Davis to a consultation on the case, and it was the unanimous opinion that tracheotomy was the only chance. Dr. Davis, having the instruments at hand, was invited to operate, and tracheotomy was performed. He supplied some of Aronson's antitoxin to Mr. Shannon, who injected it as follows: at 4 P.M. on the 15th fifteen minims of antitoxin were injected; at 4 P.M. on the 16th ten minims of antitoxin were injected; at 10.30 A.M. on the 18th eight minims of antitoxin were injected, and fifteen minims at 4 P.M. The rule was adopted to inject every six hours so long as the temperature remained above 100° F. On the 27th the tube was finally removed, and the child was discharged cured on Dec. 8th, 1894.

CASE 3.—A male child eight years of age was seen by Dr. Davis during the afternoon and in the evening of Nov. 20th, 1894. The case was considered from the first to be very grave. The temperature was 102.4° F., the tonsils and fauces were covered with membrane, which had involved the trachea, so that the boy could scarcely utter a sound, and the inspiratory retraction was very marked. The case appeared to be quite hopeless without recourse to tracheotomy, but the parents would not consent to this. At 7 P.M. Dr. Davis injected twenty minims of antitoxin into the left forearm, and the next morning the boy was removed to the Bromley and Beckenham Fever Hospital and was discharged as cured on Dec. 8th. It should be added that, although the evidence clinically in this case was to us both conclusive, the Clinical Research Association reported upon the culture box which Dr. Davis sent as follows: "Evidence of diphtheria probable, not certain. The appearance of the culture is not suggestive of diphtheria. The culture consists: (1) of staphylococci; (2) of larger cocci, probably pneumococci; (3) of a minute bacillus; and (4) of a very few somewhat large bacilli, suggesting degenerate bacillus diphtheriae."

Remarks by Dr. DAVIS.—The three cases were all partly under my care and under that of Mr. Shannon when they were in the Bromley and Beckenham Fever Hospital. Concerning Case 1 I have suggested to a manufacturer that for the future it would be well that the shield of rubber tubes should be backed throughout with canvas; at present that part of the shield perforated with holes for the tape is not so backed. In the diagnosis of diphtheria I should be inclined to use bacteriological evidence as affirmative, but not as of negative value in cases in which the clinical aspect of the case pointed to diphtheria. Bryant's tubes were those used in the tracheotomies.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Case of Large Pelvic Hydatid successfully treated by Perineal Incision and Drainage.

An ordinary meeting of this society was held on April 9th, the President, Mr. HUTCHINSON, being in the chair.

Mr. REGINALD HARRISON described a case of Large Pelvic Hydatid successfully treated by Perineal Incision and Drainage. The patient, a physically fine and otherwise healthy man, aged forty-five years, had never suffered any illness before the present. Nine years ago he began to have trouble about the bladder and rectum. This increased to such an extent that he was compelled to resort to large doses of morphia for relief and was disabled from work. In 1893 he left Australia and came to London. Mr. Harrison saw him shortly after his arrival, at the suggestion of Dr. Batten. There was a very large tumour occupying the pelvis and lower part of the abdomen, extending almost to the umbilicus. The pain and difficulty about passing water and motions were excessive. Careful examination and the history led to the conclusion that the tumour consisted of one or more hydatid cysts. In October, 1894, an incision was made through the perineum, corresponding with a lateral lithotomy, but without opening the urethra. The cyst was

reached, and about half a gallon of fluid and cysts was evacuated. The cavity was washed out and drained. The greatest relief was experienced. The cavity gradually contracted and the wound healed. The patient was now in perfect health. The question for consideration in the case of such like pelvic hydatids was as to where the opening should be made—whether through the abdominal wall, through the rectum, or by incision through the perineum, as in the case related. The last method was considered to be the best.

Dr. JOHN HARLEY remarked that in the forty-ninth volume of the Society's Transactions he had brought together over 100 cases of hydatid tumour with a view to prove the futility of simple puncture in these cases, a method which was likely to be adopted by physicians. In the St. Thomas's Hospital Reports he had collected a further 96 cases, and all went to show that a radical cure of a hydatid cyst could not be effected without the discharge of the parent cyst, and the healing of the cavity left after its removal. Puncture was often followed by shrinkage, suggestive of cure, but later either suppuration might occur or slow contraction with all its attendant troubles.

Mr. DURHAM said that hydatids of the abdomen and pelvis were common, but cases precisely like the one previously reported were rare, and successful treatment of them was still more rare. In the case described the hydatid was fixed in the fibrous tissues between the bladder and the rectum, and was not movable, like most abdominal hydatids, except those of the liver. He referred to a case which was admitted into Guy's Hospital under his care with intestinal obstruction and difficulty in passing water. An exploratory operation was undertaken to discover the nature of the trouble, and on opening the abdomen a hydatid cyst was discovered fixed in the pelvis. He opened the cyst, evacuated its contents, and sutured the cyst wall to the abdominal wall. The patient died four days afterwards of acute peritonitis, and at the necropsy a condition was found apparently much like that in Mr. Harrison's case.

Mr. WARRINGTON HAWARD said that a complete cure depended upon the completeness of the evacuation of the cyst. He could not help thinking that in some cases of pelvic hydatids drainage would be very difficult from the perineum. He had to treat a case of pelvic hydatid a few years ago, in which he was able to be confident of the diagnosis because another hydatid cyst existed higher up in the abdomen. In that case he hoped that a complete removal of the pelvic hydatid would have been possible, but the lower part of the cyst was intimately connected with the bladder and rectum, and its pressure on the former viscus had caused retention of urine. If a pelvic hydatid projected up into the abdominal cavity it was better to open the peritoneum and stitch the cyst to the abdominal wall; there would then be no difficulty about cleansing the abdominal cavity and drainage; besides, the abdominal section would render it possible to decide whether other hydatid cysts were present or whether the cyst itself was removable, as in a case recorded by Mr. Jonathan Hutchinson, jun.

Mr. TARGETT gave the reasons which induced him to regard all these cysts as having their origin between the muscular coat of the bladder and the sheath of the rectovesical fascia. By dissection of all available specimens he had shown that the cysts lay in this position, and in certain dry specimens the vasa deferentia were seen to be separated from the bladder by the cyst. By experiment he had found that it was easy to make such a separation; the finger easily separating the fascial sheath from the vesical muscular wall. In certain cystic protrusions and malignant growths of the bladder developing backwards there was a similar disturbance of the relation of the vasa deferentia to the bladder wall. Hydatid cysts could not arise secondarily in this position. They might rarely begin, as Dr. Fagge had described, by falling into the pelvic cavity after perforating the walls of the stomach, but this method of origin must be very rare. In the cysts which arose under the pelvic fascia the embryos were deposited from the venous plexuses, and the same thing was true with regard to hydatids of bone; they were usually found in the cancellous ends of long bones or in the vertebrae. In bone they were commonly primary, and were often the only hydatid deposit in the body. In Mr. Hunter's case the bladder projected eight inches above the pubes, and a recent dissection showed it to bear the same relations to the vesiculae seminales as the other specimens referred to.

The PRESIDENT said that some years ago he had published several cases in which recovery resulted from a single aspiration. One such case of hepatic hydatid he some years later

had to treat by evacuation. At the present time he was prepared to agree generally that evacuation should be practised whenever the cyst was large or the hydatid dead. He had seen several instances in which hydatids were passed by the urine.

Mr. HARRISON, in reply, said that the question whether abdominal section should be performed was carefully weighed. The length of time which the cyst had lasted, the downward pressure which it had exerted, and the ease with which the dependent portion of the cyst could be reached, led him to the conclusion that the perineal method was the best.

MEDICAL SOCIETY OF LONDON.

Congenital Chorea. — Facial Hemiatrophy. — Friedreich's Disease. — Case after Removal of a Papilloma of the Bladder by Suprapubic Cystotomy. — Syphilitic Disease of both Knee-joints. — Large Renal Sarcoma from Child aged Three Years. — Subcutaneous Nodules in an Infant. — Devergie's Pityriasis Rubra Pilaris. — Rudimentary Ear. — Macrocheilia. — Restoration of Nose by means of Transplanting part of Middle Finger of Left Hand.

An ordinary meeting of this society, devoted to the exhibition of clinical cases, was held on April 8th, the President, Sir WILLIAM DALBY, being in the chair.

Dr. G. JOHNSTON showed a boy aged twelve the subject of Congenital Chorea. He was born at term, the labour being natural, and the movements had continued ever since, involving the arms, legs, and face, and occasionally he had long shivering inspirations. The movements, though bilateral, were most marked on the left side; they ceased during sleep. There had been no fits and no rigidity, and the deep reflexes were brisk but not exaggerated. — Dr. A. GARROD said that he had a case under his care which precisely resembled the case shown. In his patient there was feeble mental development, but the child was by no means an idiot. — Dr. SHUTTLEWORTH said that the case was interesting because, together with the chorea, there were athetotic movements suggestive of lesion of the Rolandic area; the boy was nevertheless free from spastic rigidity. The London School Board had established several centres where children of this class could be trained.

Dr. BEEVOR showed a case of Right Facial Hemiatrophy in a girl aged twenty in whom there was no family or previous history of importance. Two years ago two teeth in the right upper jaw decayed and broke away, and six months later, without any injury, she noticed a dimple in the right cheek, which had gradually increased till now. There was marked thinning of the cheek, with falling in of that side, the measurement from the middle line of the upper lip to the meatus auditorius externus being a quarter of an inch less on the right side. The muscles of the face and for mastication were normal, and reacted to faradisation; in fact, the former reacted to a weaker current on the right than on the left side. The tongue and soft palate were normal. The bones of the face and the nasal cartilages were not affected. Sensation to touch, pain, heat, and cold was normal. Taste was not affected. The disease was considered to be in the trophic fibres of the fifth nerve, which, according to Mendel, were in the upper root of this nerve.

Dr. LEONARD GUTHRIE showed a boy aged nine years who presented early symptoms of Friedreich's Disease. There was no family history of the complaint. The symptoms dated from his learning to walk at the age of three. They were: (1) unsteadiness on standing markedly increased when the eyes were closed and the heels kept together; (2) a reeling gait and inability to "toe a plank"; (3) slight rhythmical tremors affecting the whole body and increased on exertion; (4) slight incoordination of the hands in executing fine movements; (5) complete absence of knee-jerks. Sensation was everywhere normal. Muscular sense was unimpaired. There were no ocular symptoms and no deformities. Speech and intelligence were unaffected. The sphincters acted normally. No definite tabetic pains had occurred. Headache and vomiting were absent. He had been under observation for four months, and the symptoms were slightly on the increase. The differential diagnosis of the case was discussed. Dr. HECTOR MACKENZIE said he had exhibited a similar

case which was an isolated one, no other member of the family being attacked. — Dr. ORMEROD said that it was probably a case of Friedreich's disease, although it appeared to be diagnosed by two symptoms only—namely, a peculiar gait and absence of knee-jerk. Other symptoms described in Friedreich's original cases were absent, such as peculiar speech, nystagmus, and family proclivity. — Dr. BEEVOR agreed in the diagnosis and said that these cases were now recognised much earlier than they used to be. — Dr. COLMAN remarked that two other symptoms were present—a general tremor of the trunk when at rest and slow nodding movements of the head and trunk.

Mr. SWINFORD EDWARDS showed a case after Excision of a Papilloma from the Bladder. The patient was a man aged fifty-four, who had suffered from intermittent hæmaturia commencing three months ago; there was also right lumbar pain. The growth was removed by suprapubic cystotomy and the wound had quite healed.

Mr. WARING showed a woman forty-five years of age who first presented herself to him with Syphilitic Disease of both Knee-joints. Later she returned to the hospital, and an affection of the knee-joints was found similar to that seen in Charcot's disease. There was marked swelling, especially of the right knee, but the knee-jerks were exaggerated. There was increased vesical irritability. The syphilis had been acquired ten years previously, and had been treated with iodide of potassium, but not with mercury.

Mr. HERBERT ALLINGHAM showed a Renal Tumour weighing two and a half pounds which he had removed from the right side of a child aged three years. The child was at the present time in good health. He stated that the growth had not at present been examined microscopically. It arose from the capsule of the kidney, and the supra-renal body was free. There were no urinary symptoms and the ureter was dropped back after ligation.

Dr. ABRAHAM showed a female infant who for ten weeks had suffered from Multiple Subcutaneous Nodules. The larger ones had become directly connected with the skin, and fluctuated. They were scattered all over the body. He thought that they were multiple tuberculous granulomata. — Mr. LEOPOLD HUDSON said that he had seen three very similar cases within the last eighteen months at the Hospital for Sick Children. The last, sent him by his colleague Dr. A. Garrod, was associated, like the case shown, with a bad attack of thrush. The multiple lesions proved on exploration to be abscesses, and their evacuation was followed by a rapid convalescence.

Dr. ABRAHAM showed a boy aged six years who was the subject of Pityriasis Rubra Pilaris. The present attack had developed within three weeks. Such cases were rarely seen in children; the boy had had a similar attack two years ago, and had got well. The affection was of the xerodermic type.

Mr. ASTLEY BLOXAM showed a child sixteen months of age with a Rudimentary Ear on the right side. There was also a dimple between the angle of the jaw and the mouth. — Sir WILLIAM DALBY said that he had seen a number of these cases. Sometimes there were as many as three rudimentary ears on the same side. Occasionally in such cases as that shown there was imperfect development of the labyrinth on the opposite side.

Mr. BLOXAM then showed a girl aged twelve who had a Deformity of the Chin, which had existed from birth. It involved the cheek to a slight extent, and consisted of some dilated lymphatics with enlarged bloodvessels as well. He proposed to dissect it out.

Mr. BLOXAM lastly showed a middle-aged man whose Nose had been destroyed by Tertiary Syphilitic Disease. An attempt had been made at Netley to form a new nose from the skin of the forehead, but this had not been very successful. An amputated child's finger was then attached to the part, but this refused to adhere. The middle finger of the man's left hand was stiff and useless to him, so an incision was made down its anterior surface and the tendons dissected out. The finger was then attached in the position of the nose, the arm being supported by plaster of Paris. Later the soft tissues at the root of the finger were divided on each side by the actual cautery and the bone divided, the distal phalanx with the nail having been previously removed. The ultimate result was the formation of a very presentable nasal organ, an ala on each side being subsequently fashioned from the tissues of the cheek.

OBSTETRICAL SOCIETY OF LONDON.

Temperature, Pulse, and Respiration during Labour and Lying-in.—Ovariectomy in Women over the age of Eighty Years.—Exhibition of Specimens.

A MEETING of this society was held on April 3rd, Dr. F. H. CHAMPNEYS, President, being in the chair.

The following abstract of a paper by Dr. PROBYN-WILLIAMS and Mr. LENNARD CUTLER upon Temperature, Pulse, and Respiration during Labour and Lying-in was read. The writers first considered the effect of labour. With regard to temperature they find that their results coincide with those of Dr. Giles. With regard to pulse they find: 1. *Rate*: The low rate of the pulse after delivery, as given in the text-books, is exaggerated. In one hundred cases of normal labour observed in connexion with this point they found that in 76 the rate was diminished, in 11 it remained stationary, and in 13 it was increased after the end of the third stage. In this series the average decrease between the rates during the first stage, and half an hour after the end of the third, was eleven beats per minute (from eighty-nine in the first stage to seventy-eight after delivery). Parity and the length of labour have some influence on this fall; and after the administration of chloroform during labour it is common to find the pulse remaining high after delivery. In 19 cases of post-partum hæmorrhage there was an average rise of nineteen beats per minute (seventy-eight during labour, ninety-seven after delivery). 2. *Tension*: This, as estimated by tracings made with Dudgeon's sphygmograph, is usually above normal during labour, but is occasionally low, notably in one case in which delivery was followed by considerable hæmorrhage. *Respiration*.—After delivery there was on the average a fall of one respiration per minute (23 during labour, 22 after delivery). After the administration of chloroform this decrease was not observed. The effects observed in connexion with lying-in were as follows:—*Temperature*.—The average temperature of 100 cases varied between 98° and 99°F., being higher in the evening than in the morning. The highest average temperature was reached on the first day and was higher in primiparæ than in multiparæ. Rupture of the perineum had no appreciable effect on the temperature during the puerperium. *Pulse*.—(1) *Rate*. The writers do not agree with the statements in the text-books that the pulse is normally very slow during the first week, but found that the average rate of 100 cases was never lower than 72. The pulse-rate was faster in the morning than in the evening throughout this series. (2) *Tension*. In a few cases the tension is diminished by delivery; but in the majority it is increased. Whatever may be the tension of the artery during labour, and whether it rise or fall after delivery, within twenty-four hours it has always increased so much that it is at least as great as, and generally greater than, the tension during labour. This increased tension may persist throughout the puerperium, and commonly lasts longer in multiparæ than in primiparæ. *Respiration*.—The rate of respiration was found to vary between twenty and twenty-two per minute. It tends to follow the pulse-rate in being higher in the morning, and not the temperature, which is higher in the evening.—Dr. DAKIN congratulated Dr. Probyn-Williams and Mr. Lennard Cutler on their very important paper. Their observations on the temperature, which were made under circumstances most favourable for accuracy, showed what was the typical chart of a lying-in woman—namely, one differing in no way, except for some slight exaggeration of the evening rise and morning fall, from that of a person in ordinary health. The chart of the cases where perineal rupture was present showed the efficacy of the antiseptic methods in use at the General Lying-in Hospital at the present time, for it did not differ practically from that of cases where there was no rupture. The pulse-rate which they found to be the average was perhaps more interesting, as it was opposed in some degree to what was stated in the text-books. Their results were, however, what most of those who had large experience of lying-in women would expect. As regarded the tension of the pulse, they again were at variance with what had been hitherto accepted. Fritsch and Meyburg found that the tension was diminished; and it became difficult to reconcile this with the slower rate. Dr. Probyn-Williams and Mr. Cutler's results showed that the pulse obeyed the ordinary laws of the circulation in these circumstances, and explained the tendency to a slow

pulse by the high tension always present. Their results explained also the frequency of pulse which often preceded post-partum hæmorrhage, if it were assumed, as it fairly might be, that the suddenly increased arterial tension which normally occurred was due to a retraction of the vessels in unison with the retraction of the uterus. Then, if retraction of neither uterus nor arteries were complete, there would be, as happened in the cases in the paper, a low tension and rapid pulse on the one hand and a relaxed and bleeding uterus on the other. It is possible that the increased rapidity observed by Dr. Probyn-Williams and Mr. Cutler after the administration of chloroform was due to diminished tension, and the tendency to post-partum hæmorrhage, believed by some to exist in women who have had chloroform during their labour, might be thus explained. Dr. DAKIN had never seen this effect from the drug. One effect of its administration was that the child at birth was often very lethargic, and did not begin to cry vigorously at once without considerable stimulation.—Dr. REMFRY considered that the rise in pulse-rate after chloroform might be due to the fact that in the cases recorded chloroform had only been given in tedious labours and when instrumental or other manipulations had been necessary.—Dr. HORROCKS thought the increased rate of the pulse in post-partum, as in any other form of hæmorrhage, was physiological. Theoretically, half the amount of blood in the body could do the same work in a given time if it were circulated with double the velocity. The increase in number of heart beats was an attempt to increase this velocity *pari passu* with the loss. The precise way in which the loss of blood set up the increased rate was not perhaps known, but no doubt it was through the vaso-motor system. He could not agree with Dr. DAKIN regarding retraction of the heart and arteries. As a matter of fact, so long as the heart was completely refilled with blood there was no retraction. If it were under-filled there would be some retraction, and if it were not refilled at all there would be complete retraction during each diastole. The increased size of the left ventricle during pregnancy was a hypertrophy, and its subsequent diminution was an involution.—Dr. AMAND ROUTH asked for more information as to the effect of chloroform upon the temperature of the lying-in woman. He thought the administration of chloroform by lowering the heat of the body might in a measure account for the difficulty in reviving children after its use, which, as Dr. DAKIN had stated, was not infrequently observed.—Dr. DUNCAN agreed with Dr. Probyn-Williams and Mr. Cutler in questioning the accuracy of the statement made in text-books that the pulse-rate became slower after delivery. In years gone by he (Dr. Duncan) used to dread post-partum hæmorrhage if the pulse kept up to 110; but he found his fears were groundless, as he had never had a case of this accident, whilst a good many of his patients had a pulse of over 100 for some hours after delivery. He thought a high pulse-rate was met with most often in the upper classes of society, where a neurotic temperament was not rare.—The PRESIDENT said that a paper of this kind was much needed to test and correct accepted views, which were apt to be quoted from book to book without sifting. The chief point in debate seemed to be the pulse. In his experience this was often rapid, especially after excitement, either mental or bodily, without any undue loss of blood. But in this case the beats were distinct and the tension good. The pulse of hæmorrhage was running, the beats not well separated, and the tension low. Such a pulse often preceded hæmorrhage and betokened a general vaso-motor condition affecting the heart, arteries, and uterus.

Dr. LEONARD REMFRY read a paper on Ovariectomy in Women over the Age of Eighty Years. Ten cases were recorded, all of whom had recovered. The list included operations in England, America, Australia, and Germany. One patient, aged eighty-three years, suffered also from epithelioma of the vulva. Dr. Remfry saw her in August, 1894, and the epithelioma was at once freely removed. In November there were no signs of recurrence, and the internal tumour being larger, ovariectomy was performed; her convalescence was satisfactory. The paper concluded with some details of the various cases and remarks on the powers of resistance in aged people.—Mr. BUTLER SMYTHE congratulated Dr. Remfry on the success of his case complicated with epithelioma, and asked if any mental symptoms had been observed previously to the operation. The patient had been under his care on two occasions, but had absolutely declined to have the tumour

removed. Her mind then seemed to be exceedingly weak, and her conduct and language extraordinary. She had been to several hospitals "to show herself to the doctors," but would not submit to any operative measures beyond aspiration of the cyst, which was twice performed. It was most gratifying to hear from Dr. Remfry that up to the present time there had been no recurrence of the epithelial growth.—Dr. LEWERS hoped that the after-history of the case as regards the vulvar epithelioma would be given to the society, as in his experience recurrence was much more likely to occur early than in cases of epithelioma of the cervix. Dr. Lewers mentioned a case under his care where, after apparently complete removal, recurrence took place in the inguinal glands five months after operation.—Dr. HEYWOOD SMITH said that in his case, referred to in the paper, the tumour was of enormous size (47 lb.), and prevented the patient from moving freely about. The adhesions to the abdominal wall were very strong, so that he had to leave a piece of the cyst wall the size of a dinner plate attached to the inside of the abdomen.—The PRESIDENT said that it must be remembered that people of eighty years and upwards were selected cases; they had outlived their contemporaries, and might be expected to be unusually sound. Dr. Remfry's paper illustrated the fact that cases which would not seem favourable often turned out well, and that a selection of ovarian cases on *a priori* grounds was unsatisfactory. The good results of operation for ovarian tumour with pregnancy illustrated the same fact.—Dr. REMFRY, in reply, said that the mental condition of the patient with epithelioma was perfectly satisfactory during her stay in hospital, except during convalescence, when she was irritable and difficult to manage for three or four days. There had been no recurrence of the epithelioma, which was excised in August, 1894. It was always necessary to verify a patient's age by obtaining if possible the birth certificate. He considered that after ovariectomy in old women nutrient enemata should be administered in order to prevent shock.

The following specimens were shown:—

Dr. CULLINGWORTH: (1) Embryo and Clot from a Tubal Abortion; (2) Diffuse Uterine Myoma.

Dr. DUNCAN: (1) Myoma undergoing Myxomatous Degeneration removed by Hysterectomy; (2) Oedematous Myoma removed by Hysterectomy; (3) Double Tubo-ovarian Cysts; (4) Dilated Tubes and Cystic Ovaries (early stage of tubo-ovarian cysts).

Dr. LEWERS: Tubal Gestation of Three Months operated on before Rupture.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Treatment of Empyema in Children.—Secondary Malignant Disease of the Lung or Pleura.

A MEETING of this society was held on April 5th, the President, Dr. BANNING, being in the chair.

Dr. COUTTS read a paper on the Treatment of Empyema in Children. He considered that there was a chance of cure by aspiration in cases with small cavities that are recognised in their early stages. If there were no improvement after two aspirations he thought that the method was inadvisable. Statistics were given of twenty-seven cases treated by simple incision, and of sixty-one cases treated by rib resection. Notwithstanding the unfavourable results of the former as compared with the latter, Dr. Coutts thought it should be tried in the more debilitated cases. After opening the chest he advocated washing out not only in cases with offensive discharge but in those of large dimensions with high temperature. He gave statistics of forty-three cases of empyema in children under the age of two years with twenty-seven deaths. Empyema is in itself so fatal at an early age that the responsibility for the high mortality does not rest on one operation or another. Although here again the statistics were favourable to the method of rib resection, Dr. Coutts was, on the whole, inclined to the opinion that simple incision was preferable in these infants.—Dr. MAY referred to the treatment of empyema after operation by immersing the patient in a warm bath.—Mr. BIDWELL mentioned that he had known caries of rib to follow resection for empyema in children, and therefore he was inclined to recommend simple incision in any case where the pus was not fetid; he thought, too, that the patient's stay in hospital was shorter after

simple incision than after resection of rib. Washing out was only employed when the pus was offensive, and in children he had found a warm bath of bichloride of mercury (1 in 10,000) very satisfactory. He had treated two cases by washing out combined with immediate closure of the wound; in one case the result was satisfactory after a second operation, and in the other resection of rib was subsequently required.—Dr. COUTTS replied.

Mr. STEPHEN PAGET read notes of three cases of Secondary Malignant Disease of the Lung or Pleura. Case 1: Early stage of cancer of the pleura, secondary to cancer of the breast, with a note on the removal of the whole mammary gland without removal of the nipple. Case 2: Advanced cancer of the pleura with pleural effusion, secondary to cancer of the breast, with a note on the value of repeated aspiration in such cases, and on the sudden sleep that sometimes follows the sudden return of the lungs to their natural action. Case 3: Huge sarcoma of the lung secondary to subperiosteal sarcoma of the femur, with a note on the possibility of making a diagnosis in this case between a solid growth and an effusion; and on the influence, if any, of amputation at the hip-joint in preventing recurrence of the disease in these cases, the value of the inhalation of oxygen, and the use of Dr. Coley's erysipelas toxin. He said that the cases showed the value of a medical opinion in a surgical case, and of a surgical opinion in a medical case. They also raised important questions as to the diagnosis of these cases, and as to their treatment, both preventive and palliative.—Mr. MACADAM ECCLES pointed out the frequency with which recurrence occurred above the line of incision after amputation of the breast for cancer. With regard to the utility of amputation at the hip-joint for sarcoma of the thigh, he referred to two cases which were free from recurrence two and a half years after operation.—Mr. BIDWELL deprecated the practice of leaving the nipple when amputating the breast for cancer; he also advocated the complete removal of the pectoral muscle in all cases where the growth invaded the muscle.—Mr. PAGET replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Three Cases of Laryngeal Paralysis.—Graves' Disease.—Chronic Pharyngitis.

A MEETING of this society was held on March 20th, Dr. J. S. TAW, President, being in the chair.

Mr. GRAY read a paper for Mr. STEWART and himself on Three Cases of Laryngeal Paralysis. They divided laryngeal paralysis into: (1) neuropathic paralysis—(a) from central lesions, (b) from lesions of the superior laryngeal nerve, and (c) from lesions of the recurrent laryngeal nerve; and (2) myopathic paralysis. They illustrated this division by cases of paralysis of the superior and recurrent laryngeal nerves respectively and also a case of bilateral abductor palsy, which they claimed for the myopathic variety.—They also read a short communication on the Surgical Treatment of Graves' Disease, with some Considerations on its Pathology. They narrated two cases of Graves' disease for which isthmoidectomy had been performed, with very rapid improvement in the patients' symptoms. They discussed the alternative operation of removing half the gland with the isthmus, and claimed for isthmoidectomy equal efficacy and much less risk. Referring to the pathology of Graves' disease they passed in review the various theories laid down and arrived at the conclusion that the theory that answered all the facts best was the one which held that Graves' disease is a primary disease of the thyroid gland, and that the symptoms are due to a hyperplasia with exaggerated functions of the gland—in short, to hyperthyrea, just as those of myxoedema are now universally agreed to be due to the opposite condition of the thyroid, athyrea. They gave all the arguments for this view—especially the appearances seen microscopically in the gland (as summarised by Professor Greenfield in the Bradshaw Lecture of 1893)—the known symptoms of overdose of any of the thyroid preparations and the result of operations.

Mr. MACKIN read a paper on Chronic Pharyngitis and claimed that in the causation and maintenance of this condition the gouty and rheumatic diathesis was in the majority of cases the most prominent factor.—The President, Miss

Gray, Dr. Cattle, and Dr. Tresidder spoke, and Mr. Gray and Mr. Mackie replied.

Some Points connected with the Question of Operation in Acute Intestinal Obstruction.

A MEETING was held on April 5th, Dr. J. S. TEW, President, being in the chair.

An address was delivered by Mr. W. H. A. JACOBSON, of Guy's Hospital, on Some Points connected with the Question of Operation in Acute Intestinal Obstruction. He drew attention to the great mortality attending these operations and inquired why progress had not been so rapid as in many other branches of abdominal surgery. The small intestine was a peculiarly vital part, and in cases of obstruction there was not only local damage, but also far-reaching collapse on account of the important nerves at the root of the mesentery. It was futile to compare operations for the relief of internal obstruction with herniotomy; in the latter the operation was practically extra-peritoneal, while in the former the sac was the whole peritoneal cavity. A large proportion of cases were, and must necessarily remain, fatal, partly on account of the inherent vulnerability of the parts and the attendant collapse, and partly on account of the inability of surgical skill to detect or relieve the seat of strangulation. Cases of obstruction by bands, some internal herniæ, some cases of gall-stones, and some intussusceptions were among those most favourable for operation; while the least hopeful, or almost hopeless, were cases in which complicated snaring and matting of the small intestine or severe volvulus were found. Another favourable class for operation was that in which acute obstruction supervened upon an unsuspected chronic obstruction. The unsatisfactory results of operation had led many practitioners to advocate a purely medical treatment. No doubt some cases so treated recovered, but they were probably cases of incarceration, not of strangulation. Enemata by the long tube were useless for severe acute obstruction. In discussing the question of operation he remarked that every case should be submitted to exploration if the patient's condition warranted it, and, provided the surgeon had a clear knowledge of how far it was safe to go, he preferred a tolerably free incision and described the method of rapidly searching for the obstructed point. No operation should be unduly prolonged; if the obstruction was not readily found it was better to open a distended coil, insert a Paul's tube, and close the abdomen.

Reviews and Notices of Books.

King's College Hospital Reports. Vol. I., Oct. 1st, 1893, to Sept. 30th, 1894. Edited by NESTOR TIRARD, M.D., F.R.C.P.; W. WATSON CHEYNE F.R.C.S., F.R.S.; JOHN PHILLIPS, M.D., F.R.C.P.; and W. D. HALLIBURTON, M.D., F.R.C.P. London: Adlard and Son. 1895.

THE appearance of the names of four editors upon the title-page of this volume seems to have been necessitated by the complex nature of the task undertaken. From the subtitle we learn that the work comprises the Annual Report of King's College Hospital and the Medical Department of King's College, and, as the College includes numerous scientific laboratories, the labour of collecting material must have been considerable. That this should be the first volume of reports issued from this source may cause some surprise, which will not be diminished by the most cursory examination of the value of the various papers and reports. Professor Watson Cheyne, in a post-prandial speech, considers that King's men are "too modest and retiring." The clinical reports alone indicate that there may be some truth in this remark; but they afford evidence of abundant vitality and good material and render full justification for the appearance of another annual volume, in spite of the crowded condition of medical literature. The first paper is an instalment of a historical sketch of the college and hospital by Professor Curnow, which is especially interesting in tracing the origin of King's College, University College, and the University of London. Dr. Beale writes on the Curable Stage of some Incurable Maladies, chronic rheumatoid arthritis receiving the greater share of attention. Dr. Duffin contributes Clinical Considerations on

the Abstraction of Blood. Dr. Tirard writes a short note upon a case of Functional Albuminuria met with in hospital work and illustrates the subject by a brief comparison of similar conditions which have come under his notice. Dr. Ernest White deals with the importance of Psychological Medicine in relation to the General Practitioner. A paper on Sneezing, read by Dr. Greville MacDonald before the King's College Medical Society, is conceived in a lighter vein, but is essentially practical. Dr. Silk is equally satisfactory in his exposition of the Principle of Selection as applied to the Administration of Anæsthetics. Mr. McHardy gives further experiences of the Artificial Maturation of Immature Senile Cataract by Trituration, but somewhat impairs the appearance of the book by marginal notes. Pelvic Suppuration in the Female supplies Dr. John Phillips with a subject for an instructive paper. Mr. Burgbard gives his results in the Treatment of Gonorrhœa and Gleet by means of the Urethroscope. Mr. G. L. Cheatle has a short illustrated paper on Bursitis, and Dr. Aldren Turner gives an interesting account of the Value of the Discoveries of Sir Charles Bell. The medical and surgical reports have not been arranged upon the same system, but there may be much to be said in favour of each plan. Dr. Whitfield, the medical registrar, gives rather full notes of selected cases of interest. Mr. Cargill, the surgical registrar, has prepared a somewhat elaborate General Table of Surgical Cases, while Messrs. Rose, Watson Cheyne, Carless, and Beale deal more fully with the cases of interest that have been treated by them respectively. Dr. John Phillips supplies reports upon the Obstetrical Department and the Gynæcological Wards. Reports by Dr. Hayes and Messrs. McHardy, A. H. Cheatle, and Underwood deal with special departments and are somewhat brief. Dr. Dalton gives a careful classification of the work in the Pathological Department. The reports from the various Practical Departments and Laboratories, in the table of contents attributed to Dr. Halliburton, appear to have been written by different hands; at any rate, other initials are attached to the Historical Sketch of the Anatomical Department, a sketch which will please a former generation of students by its kindly picture of Partridge. A somewhat novel feature is supplied by the pages which record What Old King's Men are Doing—a list likely to be studied with interest by old King's men. The volume reflects great credit upon all concerned in its production, especially when the initial difficulties of such an undertaking are considered. In the preface the editors appeal for "sympathetic indulgence" in starting a new venture. Careful consideration of the work in this volume leads to the conclusion that sympathy should be extended rather to those who in future will have to maintain the same high standard.

A Handbook of Hygiene. By Surgeon-Major A. M. DAVIES. London: Charles Griffin and Co. 1895.

DURING the last few years a very large number of works on hygiene and public health have been issued from the press, and the cry is "Still they come." We are glad, however, to welcome Surgeon-Major Davies's book, for we feel that he has had ample opportunity during the years in which he was assistant-professor in the school of hygiene which Parkes founded to make himself one of the masters of the science, and he has therefore a right to speak. The author claims but little originality; his aim has been to make himself acquainted with what has been written by approved authorities, to compare and weigh different statements, and to digest the information into as small a compass as seemed advisable, while omitting nothing of real importance. The book, which is about the same size as Willoughby's "Health Officer's Pocket-book," contains some 580 pages and will doubtless be very useful to medical men and to officers of the

Army Medical Staff serving abroad, where, as often happens, only books of a minimum size can be carried. Taking the old saying that "a man can live three weeks without food, three days without water, and three minutes without air" as his guide, Surgeon-Major Davies has considered the three chief needs of man in the order of their relative importance. There are also chapters on the Removal and Disposal of Sewage, on Clothing, on Habitations, on Personal Hygiene, on Soils and Sites, on Climate and Meteorology, on the Causation and Prevention of Disease, and on Disinfection. The appendix contains a useful comparison of metrical and English weights and measures, and notes on solutions for chemical analysis, on cultivation media, and on some of the elementary points in statistics. Though all the subjects treated of are necessarily condensed, the book is well and clearly written, and is pleasant to read. The author has succeeded in bringing the work wonderfully well up to date—not an easy matter in these days of rapid progress. It is sufficiently illustrated and we feel we can recommend it. The book is appropriately dedicated to the memory of Dr. F. de Chaumont.

LIBRARY TABLE.

Text-book of Anatomy and Physiology for Nurses. By DIANA CLIFFORD KIMBER, Graduate of Bellevue Training School, Assistant Superintendent, New York Training School. New York and London: Macmillan and Co. 1894.—This work is written in a clear and easy style, and is fully illustrated with excellent engravings. The various chapters follow the order usually adopted in anatomical treatises, commencing with the bones and passing on to the joints, muscles, sanguineo-vascular system, lymphatics, respiratory organs, alimentary canal, urinary organs, skin, nervous system, organs of special sense, and finally the female generative organs. With the description of these several parts is incorporated an ample and very satisfactory account of their mechanical and physiological functions. The book consists of 260 large octavo pages, and probably contains more anatomical and physiological information than is likely to be required by the class of readers for whom it is designed. A considerable amount of histological detail is introduced, and some paragraphs on embryology as well. The authoress expressly defends this in her preface, but many persons will nevertheless adhere to the opinion that the majority of nurses will profit but little by instruction on the subject of the peritoneal endothelium (p. 91), or multipolar nerve cells (p. 200), or the embryonic development of bloodvessels and corpuscles (p. 117). Amid the profusion of highly-finished engravings the reader will perhaps feel the absence of a simple diagram showing the surface areas corresponding to the contents of the chest and abdomen—an extension, in fact, of that shown on p. 154. The volume is handsome in appearance and leaves nothing to be desired in point of mechanical execution; but its treatment of the subject is far too copious and extensive for the purposes of the average nurse, and the next edition will be greatly benefited by free retrenchment of anatomical details.

Posological Table. By WILLIAM CRAIG, M.D. &c., Edin. Edinburgh: E. and S. Livingstone.—This is a useful little book, containing a tabular arrangement of all the Pharmacopœial preparations, with their doses and methods of administrations. A table on Poisons and an Index of Diseases with Appropriate Remedies are included. In our opinion tables of the latter class are of very little use, especially when under the head of Diseases we find symptoms such as "dropsy" and "jaundice" tabulated.

The Last Abbot of Glastonbury and his Companions. By FRANCIS AIDAN GASQUET, D.D., of the Order of St. Benedict. London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd. 1895.—These biographical sketches carry the reader back to

monastic life in England during the reign of Henry VIII. The commanding position of Glastonbury Abbey among the English religious houses naturally entitles its Abbot to the chief place in the volume, the other subjects of portrayal being Hugh Cook, last Abbot of Reading, and Thomas Marshall, or Beche, last Abbot of Colchester. The author considers that the origin of Glastonbury Abbey was of a date previous to the Christianising of the Anglo-Saxon settlers in England. He does not occupy himself with its history until the year 1525, when Cardinal Wolsey appointed Richard Whiting, a monk belonging to the community, to be the abbot. Great political and ecclesiastical upheavals were at that time imminent. In less than ten years Henry defied the authority of the Pope, and required the clergy of the kingdom to swear allegiance to himself as head of the Church. Abbot Whiting and his community, fifty-one in number, accordingly made the required declaration in 1534. Henry, however, resolved to include in his anti-papal measures the destruction of the monastic system, and his agents found that the law of royal supremacy provided an easy means of attack. Abbot Whiting, having been interrogated at the Abbey by special Royal Commissioners, was sent to the Tower in 1539 on a charge of treason, and in November of that year was executed at Glastonbury and his body quartered. Such lamentable cruelties seem to have been inseparable from religious strife in that intolerant age; the wholesale suppression of the monasteries was, moreover, a ruthless act unworthy of a powerful monarch and a great misfortune to the cause of art and learning. The volume is profusely illustrated, chiefly with charming photo-engravings of monastic architecture.

MAGAZINES AND REVIEWS FOR APRIL.

The Phonographic Quarterly Review.—The success which has attended the efforts of a few medical men to form a Society of Phonographers and the interest which several prominent members of the profession have taken in the movement would lead us to suppose that phonography is destined to become a useful adjunct to medical teaching. To those proficient in the art, and even to those who have but a tyro's acquaintance with it—for the outlines are clearly and beautifully lithographed—the appreciative sketch in the quarterly before us of Dr. Jameson, C.B., written by his old teacher Dr. Gowers, will be perused with feelings of pride. It is by his own choice, Dr. Gowers tells us, that the man who is entrusted with the charge of a kingdom remains simple Dr. Jameson, the title by which he is so well known. As the circumstances under which Dr. Jameson first went to South Africa are but little known, and as an erroneous account has been given in a recently published book, we translate that portion of the article which gives the facts as told to the writer by Dr. Jameson himself. While resident medical officer at University College in 1878 one of the staff went into his room and asked him if he knew a man who would go out to South Africa to take up a partnership there. It was three months before the expiration of Dr. Jameson's two years' term of officership. For a moment he was silent, and thought, "I have no definite prospect here; it is hard to make way; this is sure." He replied, "I will take it, sir." "But you have to go at once," said the questioner. "I will take it, sir," repeated Dr. Jameson. Two days later the future administrator of the British Chartered Company's territories left England. This is so characteristic of the quiet determination of the man that it is worth recording, and has no doubt had a great deal to do with his success. "The Political Status of the Uitlander," by a Uitlander, will be found a fresh contribution to the proper understanding of an old problem, relating to the same part of the empire with which Dr. Jameson is so intimately connected. Another article well worth reading is a short account of the elements of the

hieroglyphic system used by the ancient Egyptians. It will be remembered that Dr. Thomas Young, a member of our own profession, shared with the great French orientalist, Jean François Champollion, the honour of discovering the meaning of the hieroglyphics on the Rosetta Stone and thus threw a flood of light on the meaning of ancient Egyptian writing. Dr. Norman contributes an article on the Evolution of the Post Office Savings Banks.

The English Illustrated Magazine.—The April number of this magazine has a very good list of names—George Gissing, Stanley Weyman, and Archdeacon Farrar amongst others. There is an article upon Sandwich Men, which is a pathetic account of a much-to-be-pitied class. Miss Violet Hunt, deserting her usual dialogue form, has a short story called an "Encore," which is to be commended for the absence of inaccuracy in the account of the heroine's illness. The typical illnesses of fiction writers are, as a rule, of a kind unknown to pathologists, and we are always thankful when we come across a writer who successfully avoids these pitfalls.

New Inventions.

A NEW INSTRUMENT FOR EXPLORING AND DRAINING CAVITIES.

THE instrument which I am about to describe, of which a short notice appeared in THE LANCET of March 30th in the report of the Clinical Society, has been used many times in the wards of St. Bartholomew's Hospital, and in the hope that it may prove generally useful I venture to bring it before the profession in your columns. It is intended for exploring, draining, or aspirating any cavity, is simple, free from taps and screws, portable, readily cleaned, and can be boiled in a test tube. The instrument consists of a cannula and trocar made in three sizes. The cannula differs from Potain's in having the mount smooth inside, so that the air-tight chamber on the trocar fits directly into it without intervening tap (Fig. 2). The trocar (Fig. 1) has a thick neck half an inch long; its air-tight chamber is a solid metal cylinder, smooth outside, and without any concealed washer or packing within; the trocar can be drawn back through it until the point is buried, but no further. Before use, a piece of rubber tubing one inch and a half long is fitted on to the mount of the cannula, and secured by a thread tied round in the groove provided. When the trocar is put inside, the rubber covers the air-tight cylinder and also the neck of the trocar; it is now ready for use (Fig. 3). The instrument is thrust into the cavity and the trocar drawn back into its cylinder (Fig. 4); in doing this it is well to hold the cylinder at A, lest it be drawn out of the cannula with a jerk. The cylinder is then given a slight twist to ensure that it is loose, and is withdrawn through the rubber tube by steady traction on the trocar; when the rubber is wet and traction is exerted steadily it comes out quite smoothly. While withdrawing the cylinder, the rubber is pinched with finger and thumb, or clamped with bulldog forceps to prevent ingress of air (Figs. 5 and 6).

The cannula is thus left in the cavity ready fitted with drainage-tube. If, now, exploration is intended, a glass syringe is inserted into this tube; if drainage or aspiration is required the tube is pinched again and the syringe replaced by a glass tube (Fig. 6) previously connected either with a long drainage-tube full of water (Fig. 6) or with a Potain's bottle. Failing the bottle, a Higginson syringe will replace it for aspiration, especially if the valves of the latter are out off and the fingers used instead. Each cannula has a blunt rod as well as a trocar to match. To clean the inside of a cannula after use, draw a few threads of soft white darning cotton through it by means of a loop of silver wire provided. Two pairs of bulldog forceps go with each set of trocars, the set being sent out in a neat metal box, which can easily be carried in the pocket. One pair of forceps is used to clamp the drainage-tube, and keep it full of water until fixed. My syringe, for exploring with my cannula, is a ten c.c. glass syringe, the glass having no metal attached to it, so that it is readily

cleaned. The plunger is of asbestos, it can be compressed by an adjustable metal disc, so as to insure always an accurate fit in the barrel. The screw cap in general use in such syringes is replaced by a rubber cork lined and capped with metal, it is more convenient than a screw cap, and is, I am told, much easier to make. The handle of the piston is very comfortable to hold. Every part of the syringe takes to pieces, and can be boiled. Attached to a hypodermic needle, such as is sent out with the trocars, by a stout rubber tube, this syringe does excellently for injecting antitoxin, and has been used for the purpose in the diphtheria ward at St. Bartholomew's Hospital. A pair of test tubes is sent out with the syringe, in which trocars, cannulae, rubber tubes, and hypodermic needle can be boiled; they have rubber caps with a slit in the top, which allow the tube to be boiled nearly full, without the water bumping out, the steam escaping through the slit. Before boiling make the slit

gape by pulling down the cap, and after, close it by pushing up the cap, and the tube will remain sterile until required. The syringe and test tubes are sent out in a box together, with or without four feet of drainage-tube; in hospitals the latter need not be carried, being always obtainable. With a box of trocars in one pocket, and the above in another, the practitioner is ready for the exploring and draining of nearly any pleuritic or ascitic effusion. For the rare cases where the syphon action of the drain-tube full of water is insufficient, and it is nevertheless necessary to withdraw the fluid without incision, he must carry or borrow a Higginson syringe. The Potain's bottle is, of course, better if at hand. The practitioner is also equipped for the injection of antitoxin, and he carries his sterilising apparatus with him. In tapping the abdomen I find it best to lay a small pillow across the patient's knees to support the instrument and keep its end well down inside. The trocars and cannulae are made by Messrs. Arnold and Son of West Smithfield, and the syringe and test tubes by Messrs. Baird and Tatlock of Cross-street, Hatton-garden.—GEORGE C. GABBATT, M.B.,

Late House Physician, St. Bartholomew's Hospital, and Hospital for Diseases of the Chest, City-road.
Little Tew, Enstone, Oxon.

THE LANCET.

LONDON: SATURDAY, APRIL 13, 1895.

THE *raison d'être* of a medical society being the interchange of opinions upon pathological, clinical, and therapeutical facts, it is clear that the members should be of one mind as to the essentials of medicine and pathology. The introduction amongst them of persons who, having gained the necessary qualifications to practise, enter upon their profession by repudiating the bases of its science, and adopt a name which affirms this openly, is both undesirable and unseemly. It was, therefore, with some surprise that we learnt a short time since that at least one of our metropolitan societies comprised some so-called "homœopaths" amongst its members. Now it seemed to us that—because as in the matter of consultation upon an individual case so also in a conference upon any question of scientific interest there can be no common ground between the homœopath and the general body of the profession—it would be important to learn whether any means were generally adopted which would ensure that such societies should be free from members of this class. Accordingly we addressed a letter to the hon. secretaries of thirty-six medical societies (eighteen London and eighteen of the leading provincial ones), asking for information, firstly, as to whether any members of the medical profession who were avowedly homœopaths were members of the society; and, secondly, whether there was any rule or regulation with reference to the admission or exclusion of homœopaths. We received replies from sixteen of the London and fifteen of the provincial societies, for which we tender our thanks to the gentlemen who sent them.

There is a striking uniformity in the information thus furnished to us. With only two exceptions the first question is answered in the negative, the majority in the direct manner, the rest more cautiously stating that they (i.e., the hon. secretaries) "are not aware" of any such members. It is within the bounds of possibility that a comparison between the various rolls of members and the names contained in the publication known as the "Homœopathic Directory" would reveal some striking concordances even in the most select of the societies. But if this be so the members in question have been careful in their action in the society, just as they are sometimes careful in their communications to medical journals, to keep their peculiar tenets in the background. There are, however, two societies, both, singularly enough, devoted to the same special line of study, where the presence of one or more homœopathic members is acknowledged. From the one society we learn that "this society has at least one member who is avowedly a homœopath"; from the other that there are three such members, two of whom joined at the formation of the society, whilst the third was elected subsequently, "and did not then practise homœopathy." In the case of this latter society two out of the three homœopathic members had offered papers for reading, but the council, after discussion, declined to have them read—a practical illustration of the incon-

venience attending the inclusion of homœopathic practitioners in the ranks of a medical society.

As regards the second question, one only of the London societies and three of the provincial have rules against the admission of homœopaths as members. In the majority of the societies reliance is evidently placed upon the fact that nomination from personal knowledge is required, and on the power of the ballot-box. Whether these safeguards are sufficient may well be questioned when consideration is given to the wholesale manner in which ballots are taken at the leading societies. There would be less chance of a practitioner of this kind in a provincial town gaining admission to a society than there is in London; but obviously the important thing is to enforce circumspection on the part of those who nominate. The metropolitan society referred to has always had the excluding regulation in its by-laws, and it is now proposed to make this by-law read as follows: "Subscribing members must be duly registered medical men, but no one shall be a member or eligible for election as such who is practising as a homœopath, or engaged in carrying on, or assisting in carrying on, any form of irregular practice, or who is resorting to any methods for procuring patients or practice which is derogatory to the practice of medicine, surgery, or obstetrics as a profession. And the council shall have power at any time to remove from the roll of the society the name of any member who shall be proved to have transgressed or to be transgressing this law."

This is explicit and is not unworthy of imitation by older and larger bodies. It is all very well for a society or its council to express or give an opinion as to the "unadvisability" of admitting homœopaths, and to open the doors to all registered medical practitioners, as most of these societies do; but then they have only themselves to blame if perchance it be shown that papers have been accepted and read by avowed homœopaths, or other "irregular practitioners," and discredit accrue therefrom to the society.

Nor is it on the ground of tenets alone that the "homœopath" should be excluded from a properly regulated medical society. The fact is that the practice of homœopathy in the strict sense is as infinitesimal as its dosage. What the profession generally have to complain of, what they justly resent, and the ground upon which they are right to decline coöperation is that in practising, as he is bound to do in every department except the limited one of drug treatment, the homœopath follows the canons of medical and surgical practice as universally laid down. He calls himself a "homœopath," and maybe he joins the staff of a "homœopathic hospital," but for all that is done in that hospital—or, for the matter of that, out of it, too—the cognomen has no real meaning, except in so far as it deludes a public only too ready to be impressed by every fanciful medical theory.

OUR contemporary, *Blackwood's Magazine*, in its last issue deals with the old but still ever fresh and insistent question, the habitual criminal, and how civilised society should deal with him. If inquiry and discussion sufficed to solve a difficult problem, and remove one of the greatest sores in the body politic, we might fairly expect to be soon rid of the habitual offender, for few questions are more frequently or more earnestly discussed; but there is reason to fear that

the progress achieved has not been at all commensurate with the efforts put forth. Our contemporary lays down three preliminary dicta—viz., first, that the present method of dealing with our habitual offenders, vagrants, beggars, and inebriates is almost, if not entirely, void of deterrent effects; secondly, that some treatment other than that carried out by our prison system is necessary; and thirdly, that reform is urgently required in our liquor laws. "Hitherto," says the reviewer, "Government inquiries and social science discussions have been conducted as if the principal point to be ascertained was how the existing habitual offenders could be improved. The greater part of the labours of the Departmental Committee now sitting seems so far to have been expended in that direction. We venture to submit that these labours would be much more profitably bestowed if they were devoted to the purpose of stopping the source of supply rather than of dealing with the ready-made offender." This is, no doubt, sound and true. The habit of crime, like the habit of intemperance, is almost, though happily not altogether, ineradicable. As in disease, so in crime, preventive treatment is much easier and more fruitful than curative treatment. We think, however, that it cannot be justly alleged against our legislators that they have been indifferent to measures intended to strike at the root of the genesis and propagation of crime. The industrial school and reformatory system, popular education, and sanitary reform have always had as either their direct or indirect object the removal of conditions that favour the development of the habitual criminal. The subject in its purely legal or political aspects is somewhat outside our province, but the writer in *Blackwood* sees clearly that it is also a question of health, hygiene, and *morale*, and to these phases of the problem we may profitably direct the attention of our readers. A great political leader once said that one of the fundamental duties of the statesman was to endeavour to make well-doing easy and ill-doing difficult. This is profoundly true, and medicine has much to say on the subject to which the statesman would do well to listen. *Ex nihilo nihil*. The habitual criminal is not a *lusus nature*, but a necessary, though deplorable, product of false and unsound conditions of domestic, social, and political life.

The reviewer says truly that one of the great causes of our social evils is that the mass of the lower classes are so deplorably deficient in the knowledge of "how to live." He urges that the children in our schools should be taught some of the frugal and thrifty habits of the poor in France and Germany, that "the rudiments of thrift and order, of thorough cleanliness and regularity in daily life, of gentleness and politeness, of kindness and consideration towards one another, should be instilled into them as the very essence of their existence." Further—and here he touches on matters regarding which the medical profession can have much to say—he urges the importance of improving the housing of the poor, of providing more light and air, open spaces, recreation grounds, and the like. This is all most true and wise, but we are happy to think that the public conscience is by no means asleep on this aspect of the question, and that immense progress has been and is being made. Our artisan population is certainly much the best housed of any European nation, and we do not think that in any country of Europe the general

principles of hygiene and sanitation have permeated the popular mind so widely as they have done in the United Kingdom. It is hardly necessary now to stop to prove that every effort put forth to render life among the lower classes brighter and more wholesome is an indirect blow at the development of intemperance and crime. This is universally admitted by everyone competent to give an opinion on the subject, and our chief present need is to stir up public authorities everywhere to enforce principles the correctness of which is indisputable. The great danger of municipal and other such bodies is that they may fail to have the courage of their convictions, and that they may allow considerations of economy or self-interest to over-ride the public welfare. One of the saddest reflections that can occur to us is the thought of how far practice in these matters falls short of admitted principles. We tamper with Nature's laws because obedience to them is very costly or very inconvenient, and sooner or later Nature takes a terrible revenge upon us.

A minor but still important phase of the evolution of crime is the difficulties which the poor encounter in obtaining wholesome and properly cooked food. There can be no doubt that bad food, intemperance, and crime represent a very common link of causation. As regards the quality of the food-stuffs offered for sale in our markets, we are probably ahead of most nations, but in knowledge of cookery and in skill in turning every food material to the best account we lag most deplorably behind. Education might do much in this particular, but it must be education directed to this specific end. Cookery-classes are now becoming general and deserve every encouragement, but, unhappily, the poor have too often neither the time nor the means to profit by them. We need the general establishment of working men's kitchens, such as those which have been founded so successfully in Vienna, where the poorer classes could obtain an appetising and wholesome meal at a minimum of cost, and we trust the day is near when such institutions will be general in this country. Facilities for popular recreation are another important item in the process of cutting at the sources of crime, and here, too, we think there is considerable progress. It is exceedingly important that popular amusements should be conducted under wholesome hygienic conditions and be kept as free as possible from morbid excitement of any kind.

While we thus lay stress on the material and physical causes that affect the production of crime, we by no means argue that these exhaust the subject. There is, of course, a moral and psychical side of the question. On this, however, we do not propose on the present occasion to enter.

AN event which created considerable interest in medical Scotland on March 28th was the business that took place at the General Council of the University of St. Andrews. There probably never was an occasion on which so large a General Council was known in this University, and there certainly was never one in which so many graduates of medicine were present at one and the same time. Graduates arrived from all parts of the country, and the station-master at Leuchars is reported to have said that he never before had had "such a number of doctors passing through his hands." The reason of so much interest had relation to the establishment of

two new medical chairs in the University, a chair of *Materia Medica* and a chair of *Anatomy*. For some time past an attempt has been made to blend the University of St. Andrews with the University College of Dundee, in order to establish a complete school of medicine, with various degrees as in the other Scotch Universities. The difficulty of making a complete union rested practically in the division of powers and of chairs, the two amalgamating bodies being largely incompatible for union. St. Andrews, as is well known, is one of the oldest and most classical of the Universities, an ancient seat of learning, quiet, retired, and by ages dignified—a school, in short, having a remarkable and ancient history. The University College of Dundee, on the other hand, is quite a modern school, well equipped, ready for work, full of youthful vigour, but in the opinion of some determined to win more than a mere partnership when united to the older body. It seemed, we understand, to St. Andrews men as if the old University were going to be transferred to Dundee, that the living University would be in Dundee, and that the ruins of St. Andrews would remain as an archaeological appendage over the water. Degrees might still be conferred with the after-ceremonial of capping within the time-honoured walls, and some antiquated chairs might still be the seats of some of the professors; but the life was to be in Dundee, and everything was to date henceforth from that active commercial centre. Most of the graduates in medicine felt it a pity to make such a vital change, but it was almost *un fait accompli*. The situation has, however, recently entered a new phase.

The late Mr. DAVID BERRY, of Coolangatta, near Sydney, a Fifeshire gentleman, left the ancient University some time ago a legacy of £100,000. There was a tendency indicated by his trustees for the University Court of St. Andrews to turn this munificent bequest to the purposes of medicine and science in the University itself. We cannot say with certainty that this was the sole cause of a rupture between St. Andrews and Dundee, but it had its bearing and has had its full share in the dispute that has been going on, and which has come now to so distinct a difference that it has been proposed to dissolve the union between the two institutions altogether, or at least to make such an alteration that they shall re-start on a different basis from that which had previously been expected. In January last, therefore, it was proposed in the University Court of St. Andrews that two chairs should be founded in the University and endowed out of the Berry bequest, to be called respectively the Berry chair of *Materia Medica* and the Berry chair of *Anatomy*, with a view to giving two *anni medici* at St. Andrews. The University Court, by a small majority, passed its resolution to this effect; but as the decision was considered even by some of the members of the University Court itself to require wider confirmation, and as it was opposed by many of the Senate, the matter came before the University General Council at the meeting held on March 23rd to which we have called attention, when the following resolution, moved by Professor PERTIGREW and seconded by Sir BENJAMIN W. RICHARDSON, was carried by 74 votes to 38: "That the General Council heartily approved of the action of the University Court in founding from the Berry Bequest

two additional chairs at St. Andrews as calculated to improve the general usefulness of the University, and resolved that every available means be taken by the Council to secure their success as well as that of the extended medical school at St. Andrews as a whole." Two amendments for negating this resolution were put to the meeting, but both were lost, and the effect of the resolution, it is believed, will be that competent professors will be elected, and that St. Andrews will be enabled to prepare medical students during their first two years of study. There will be then, with chairs already existing, chairs of *Anatomy*, *Physiology*, *Chemistry*, *Natural History*, *Materia Medica*, *Physics*, *Botany*, and *Mathematics*, all of them doing good work for students who are preparing to undergo the more practical teaching of the profession in the wards of a hospital. The seconder of the resolution advocated the new plan energetically. He maintained that these preliminary studies would take the place of the old apprenticeship system in medicine, which had its unquestionable advantages, and he urged that anatomy itself could be taught with far greater benefit elsewhere than within a hospital. Students, he contended, would be following an unhealthy study under the healthiest conditions that could be obtained, and sick people would avoid the risk of being exposed to the danger arising from the student leaving the dissecting-room to go at once round the sick ward. There was, of course, some opposition to this argument, but the majority of the voters seemed to be in favour of the change.

The decision, given on Monday last in the House of Lords, in regard to the powers of the Scottish University Commission will, of course, have to be taken into account. For the moment it seems to be decidedly in favour of St. Andrews University maintaining its present attitude.

Annotations.

"Ne quid nimis."

THE PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

It must be gratifying to Sir J. Russell Reynolds to find that his services as President of the Royal College of Physicians of London have been recognised by the Fellows, who by 76 votes out of 80 have elected him for another term of office. This practically unanimous vote will be endorsed by the profession in general, who acknowledge in the President one who has worthily merited the honours bestowed on him by his Sovereign and his College. In accordance with custom, before retiring from his year of office Sir Russell Reynolds delivered an address, reviewing the work of the College during the past year, and sketching in clear and appropriate language the main facts in the careers and the individual characteristics of those Fellows who have died during this period. It was, he admitted, an innovation to include in this list the most distinguished on the roll of Members, Dr. Greenhill, but the new departure was fully justified, not only by the fact that long since Dr. Greenhill had been selected for the Fellowship, which he had declined, but also by his singular pre-eminence as a scholar and his fine and honourable character. The pupil of Arnold, and contemporary at Oxford with A. P. Stanley and Newman, his classical attainments led him more in the path of literature than of science, and enabled him to unlock

the treasures of ancient medical writers for the benefit of his countrymen. The singularly varied career of Dr. Brown-Séquard was sketched in bold outline, and the opinion expressed by Sir J. Russell Reynolds that the fame of the successor to Claude Bernard would rest on the work done in his earlier days rather than that of his later life is doubtless true. The unobtrusive career of Dr. Little, who although a physician became through his personal affliction the leading authority on a department of orthopaedics; and the single-minded, just, and honest character of Octavius Sturges, whose election as Senior Censor (within a few weeks of his untimely death) had been universally approved as a fitting testimony to his worth; the genial Withers Moore, and the venerable Bisset Hawkins, whose name had long appeared as the oldest Fellow on the College roll; and, lastly, the industrious and painstaking career of Daniel Hack Tuke, who has left behind him many a *litera scripta* as well as affectionate regard to keep his memory green—gave material for the records of men who had worthily maintained the honour of the College of which they were distinguished ornaments. They were depicted in faithful terms by the President, than whom none could have better fulfilled the duty; and the vote of thanks accorded to him, on the motion of Sir Richard Quain, was certainly well earned.

THE PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

In electing Mr. Christopher Heath to the presidential chair the Council of the Royal College of Surgeons of England have taken a course which was very generally expected of them, which was amply justified by the public, private, and scientific character of their nominee, and which will give genuine pleasure to all sections of the profession. Mr. Heath is known to the whole of the surgical world as a fine exponent of his art, and as a wise, practical, and liberal-minded man, and we are certain that in his capable hands the office will shirk none of the responsibilities that are its inseparable burden, that its dignity will be fully maintained and its utility amply proven.

"ILLEGAL VACCINATION."

It is, unfortunately, notorious that there is a large amount of irregular and inefficient vaccination in this country, and there is every reason to believe that it is increasing. An illustration of this appears in the report of the last meeting of the Lincoln board of guardians, which had under consideration a communication from the Local Government Board containing extracts from a memorandum by Dr. Bruce Low appended to his report as inspector of public vaccination in the union. The extracts were as follows:—

"During the course of my inspection of public vaccination in the Lincoln Union it came to my notice that the wife of a qualified medical man, Christopher Montgomery Davidson, M.R.C.S., L.S.A., was in the habit of vaccinating a large number of cases at her husband's surgery. The certificates for such children were signed 'C. Davidson.' While visiting cases vaccinated by the Lincoln public vaccinator in the poorer parts of Lincoln, I and my colleague, Dr. Reese, who accompanied me, came upon children who had been vaccinated by Mrs. Davidson. Careful questioning of the mothers elicited the fact, in each of the cases we inquired into, that the children had been vaccinated and inspected by Mrs. Davidson, who took from the mother the certificate, saying she would send it to the vaccination officer. In none of the cases where we interviewed the mothers had Mr. Davidson been present at the vaccination or inspection, nor had this gentleman at any time seen the child's arm during the course of its vaccination. Vaccination officer says that Mrs. Davidson's name is Eliza, and that the character of her handwriting is of a very similar character to her husband's, in fact he cannot distinguish between them. In 1892 some 332 cases, and in

1893 395 cases were certified by 'C. Davidson.' Many of the cases done by Mrs. Davidson are stated to have only one scar. This lady vaccinates weekly, and I am told the number done by her grows, the mothers being attracted by the fact that only one mark is made when desired."

Mr. Davidson is not one of the public vaccinators, but it was decided to transmit to him a copy of the report and ask for an explanation. It is provided in the Act that a vaccination performed and certified by an unqualified medical practitioner will not protect the parents of children who obtain such certificates from being liable to prosecution. On the other hand, we opine that the General Medical Council would take notice of a qualified practitioner signing certificates of cases he has not seen. The incident further illustrates the laxity with which the term "successful" is used in application to vaccination. That "one mark," no matter how obtained, can be returned as a successful vaccination proves that the vaccination laws, however well framed as regards the public service, have no control over others, who do not hesitate to practise vaccination inefficiently at the request of persons whose sole desire is to evade the intention of the law whilst obeying its letter. The small-pox statistics of the past decade would have presented a different aspect than they do had vaccination been carried out by all practitioners with the efficiency demanded by the Local Government Board of its public vaccinators. The country will surely expect from the Royal Commission a definite pronouncement on such anomalies as are illustrated by this Lincoln case.

WHAT IS "PREMATURE DISCHARGE" FROM A FEVER HOSPITAL?

ALTHOUGH we are asking this question it may be at once confessed that we see no immediate prospect of being able to answer it; but we raise the issue as affording opportunity for some remarks upon the subject. From time to time we have narrated and discussed in our columns instances in which cases of infectious disease, notably scarlet fever, have occurred in houses shortly after the return to them of patients from fever hospitals; and the question has arisen as to whether these fresh outbreaks were due to careless discharge on the part of the hospital officials or to other causes. We are tempted once more to touch upon this extremely interesting and to medical superintendents of fever hospitals very important subject, since we notice that in recent reports to the Islington sanitary authority the medical officer of health makes reference to cases of scarlet fever which have arisen shortly after the return to certain houses of children discharged from one of the metropolitan fever hospitals. The first case to which we will refer was that of a boy who on admission to hospital was, according to the medical superintendent, suffering from eczema and not, as certified, scarlet fever. It appears, however, that the child developed scarlet fever four days after admission, and that eight weeks from the time of attack was examined for discharge. At this time the child is stated to have recovered from scarlet fever, but to have been still afflicted with an eczematous condition of the hands and feet. Sixty-two days after the onset of scarlet fever the child was discharged, and some four days later the child's sister developed scarlet fever. The medical attendant considered the discharged child had not completely desquamated, and the medical officer of health, on his attention being called to it, reported concerning the child, "His hands are desquamating profusely, while his feet are so to a much less extent." The child was returned to hospital, and the medical officer of health considered it had been prematurely discharged. The next case regarded as prematurely discharged was admitted to hospital on Sept. 22nd and sent out on Nov. 23rd. On Nov. 28th a brother with whom the child slept on the night of its discharge developed scarlet fever, as shortly afterwards did two other children. The medical officer of

health inspected the discharged child on Dec. 6th, and found on its head "three large and thick patches of dandruff, while over the eyebrows there was slight but very perceptible desquamation." With regard to the first case, there appears to have been a difference of opinion as to the meaning of certain conditions seen on the hands and feet. Profuse desquamation on the hands, nine weeks after the onset of scarlet fever, is certainly, in our experience, somewhat unusual. The second case was retained in hospital approximately nine weeks, and on being examined two weeks after discharge was said to be desquamating on the eyebrows. In both instances scarlet fever broke out in the houses shortly after the return of the patients from hospital, and it is, we think, a legitimate inference that these fresh attacks were due, directly or indirectly, to the returned cases. The question, however, would seem to be whether the appearances observed on the second child's eyebrows and head eleven weeks after attack were such as to justify the conclusion of premature discharge; or whether such conditions may not, quite apart from scarlet fever, be frequently found on children's faces and heads. Again, is there not such a thing as recurrent desquamation, and may not a patient discharged with a clear skin subsequently in a fresh environment evince a partial redesquamation? There is, perhaps, at the present time a tendency to regard the fact of scarlet fever developing in a house shortly after the return to it of a discharged hospital patient as evidence of carelessness on the part of the hospital officials; but it is against conclusions of this kind that we would here enter a protest. Before such a decision can be legitimately arrived at it is surely necessary that the details of disinfection practised at the patient's home should be thoroughly gone into, and this even in face of the fact that a discharged patient evinces signs of separating cuticle. We published in THE LANCET of April 6th a paper read by Dr. Joseph Priestley before the Epidemiological Society. In that paper he states that, although during the small-pox epidemic in Leicester he sent to their homes 120 children in every stage of desquamation after scarlet fever, not a single second case occurred. That there is sometimes carelessness in the discharge of patients we are far from denying, but at the same time we are not prepared to admit that the disinfection of houses is always carried out in a manner calculated to effect its object. These "return" cases will, experience seems to teach us, sometimes occur in spite of the utmost care, and the fault, if such it be, may at times lie at the door of the fever hospital, and at others at that of the sanitary authority. When, however, regard be had to the fact that a child discharged from a fever hospital has been for weeks inhaling a more or less highly infected atmosphere, is it not contrary to expectation, as it certainly is to experience, to suppose that any process of disinfection at present known to us, short of destruction of the patient's life, can be absolute; and would it not therefore tend to diminish the chances of "return" cases if parents were advised, where possible, to avoid placing a child fresh from a fever hospital in the same bed with a susceptible brother or sister?

THE CHITRAL EXPEDITION.

THE expedition to Chitral has begun well as far as our military success and the impression which this is calculated to have on the hill tribes, with their strong fatalistic superstitions, are concerned. But the Government of India cannot have gone into this campaign in the present state of Indian finances with a light heart, for it is evident that it will cost many lives and much money before it is over. Our quarrel is exclusively with Umra Khan, and we have to force our way through to Chitral; but there is every reason why we should try to secure, if possible, the friendship, and not the enmity, of the mountain tribes through whose territory we

must pass to get there. The political situation seems to be a complicated one, and it is most unfortunate that it has been forced upon the Indian Government by the unjustifiable action of Umra Khan. The topographical difficulties to be overcome are very great in a mountainous warfare of this nature; passes have to be scaled and taken and rivers to be crossed; and setting aside the fighting and the laborious nature of the marches, the transport of food, baggage, ammunition, and the provision of an adequate amount of water *en route* are no easy matters. The force was compelled by the political and military necessities of the case to start at once, and it is always difficult to obtain the requisite amount of animal transport on such occasions, as everybody knows who has ever taken part in such expeditions. As regards the fighting qualities of the force there can be no doubt, and there need be no misgiving in this respect. So far they have done extremely well, and there is every reason to hope that Surgeon-Major Robertson and the British garrison at Chitral are safe and can hold out until successfully relieved. Meanwhile it is satisfactory to learn that according to intelligence received at the India Office the wounded are doing well.

LAMP ACCIDENTS.

ON Friday, the 5th inst., no less than seven lives were lost owing to the upsetting or explosion of lamps. At Canning Town the mother of a family upset an oil lamp, an explosion is said to have followed, and the shop where the accident happened was at once in a blaze. The flames spread very rapidly, and five children who were asleep in one of the rooms were suffocated. The other accident was due to the explosion of a spirit lamp, two children being burned to death. The many instances which have occurred of deaths from the upsetting or explosion of lamps do not yet seem to have taught the users of lamps the obvious lesson. There are plenty of safety lamps now in the market at prices to suit all pockets, and we believe the London County Council is doing good work in the detection and destruction of lamps which are little less dangerous than a dynamite shell; but much still remains to be done with regard to the education of those who use lamps, and are compelled by stress of circumstances to buy them cheap.

THE TREATMENT OF FROST-BITE.

THE occurrence of frost-bite is more common in some parts of America than it is in England, but nevertheless it occurs sufficiently often to render a paper on its treatment one of interest to all medical men. Dr. Hermance of Philadelphia publishes his experience in the *Philadelphia Polyclinic* of March 9th. He divides the dermatitis of frost-bite into two classes, firstly, cases in which the injury is so severe that vesicles or blebs are formed; and, secondly, milder cases which go on to recovery without the formation of vesicles. Of thirty patients selected at random for consideration five applied for treatment immediately upon finding that the parts were becoming numb. The five patients were subjected, firstly, to prolonged rubbing with snow, followed by douches of ice-water, and afterwards applications of ichthyol ointment (25 per cent.). The remaining twenty-five patients did not apply for relief until the parts had begun to exhibit pain and increase of heat. Of these twenty-five, eighteen were treated with ichthyol ointment (33.3 per cent.), four with benzoated collodion, and three with a solution of nitrate of silver (10 per cent.). Twelve of the whole number of thirty cases were seen twenty-four hours after the first dressing. All had been treated with the ichthyol ointment, and all reported relief from pain experienced to a great extent immediately upon application, and lasting in most cases for more than twelve hours. Eight of these cases exhibited blebs upon the affected parts; the vesicles were punctured, the serum

drained, and a second dressing of ichthyol ointment applied. The remaining four of the first group were so completely relieved that they were discharged without further treatment. Of the remaining eighteen cases returning in from forty-eight to ninety hours after first treatment, two of the three patients who had been treated with nitrate of silver were discharged cured; two of four treated with benzoated collodion reported increase of pain, and blebs had formed; while in the other two treatment had failed to modify the course of the affection. Eleven cases thus remain unaccounted for; these were all treated with ichthyol ointment at the primary dressing, and eight were discharged after having received a second dressing of ichthyol. Of the total thirty, nine were of a serious character, in which there were lesions of the entire skin, and in some cases of the superficial fascia; these cases were treated with ichthyol ointment until the parts became raw and exposed when acetanilid ointment (10 per cent.) was applied. In a certain number of cases (five) the destruction of cutis was so great, and the disturbance of the vaso-motor mechanism so serious, that treatment failed, and nothing could be done except to wait until nature threw off the injured tissues and to assist in the meantime by keeping the parts aseptic.

IS TERRESTRIAL HELIUM A NEW DISCOVERY?

IN our issue of two weeks ago we announced the discovery, by Professor Ramsay, of another new gas, which, in company with argon, he obtained from the mineral clèveite, by merely acting upon it with sulphuric acid. This new constituent proved to give the spectroscopic characters of an element hitherto supposed to exist in the sun, to which therefore the name helium was given. Professor Ramsay has obtained a considerable quantity of this mixture, we learn, and hopes soon to be able to report upon its properties; and since helium has been regarded as much lighter even than hydrogen the determination of its actual density promises to be of unusual interest. If helium could be obtained in tolerable quantity, what an important bearing it might have in aeronautics. Thus, if it be much lighter than hydrogen its lifting power would be much greater, and the cumbersome and clumsy dimensions of our present balloon, it is easy to see, could be reduced with very great advantage. Was this wish father to the thought, we wonder, when, more than fifty years ago, Edgar Allan Poe, in his narrative of the adventures of Hans Pfaall, referred to the use of a gas much lighter than hydrogen for inflating the balloon in which he undertook his thrilling journey. The passage referring to the preparations for the balloon voyage is so remarkable in connexion with recent chemical discoveries that we reproduce it in its entirety. Thus, after referring to the purchase of numerous instruments and materials for experiments in the upper regions of the upper atmosphere, Hans goes on to write:—

"I then took opportunities of conveying by night, to a retired situation east of Rotterdam, five ironbound casks, to contain about fifty gallons each, and one of a larger size; six tin tubes, three inches in diameter, properly shaped, and ten feet in length: a quantity of a *particular metallic substance, or semi-metal*, which I shall not name, and a dozen demijohns of a *very common acid*. The gas to be formed from these latter materials is a gas never yet generated by any other person than myself—or at least never applied to any similar purpose. I can only venture to say here that it is a *constituent of azote*, so long considered irreducible, and that its density is about 37·4 times less than that of hydrogen. It is tasteless, but not odourless; burns, when pure, with a greenish flame; and is instantaneously fatal to animal life. Its full secret I would make no difficulty in disclosing but that it of right belongs (as I have before hinted) to a citizen of Nantz, in France, by whom it was conditionally communicated to myself. The same individual submitted to me, without being at all aware of my intentions, a method of constructing balloons from the membrane of a certain animal,

through which substance any escape of gas was nearly an impossibility. I found it, however, altogether too expensive, and was not sure, upon the whole, whether cambric muslin with a coating of gum caoutchouc was not equally as good. I mention this circumstance because I think it probable that hereafter the individual in question may attempt a balloon ascension with the novel gas and material I have spoken of, and I do not wish to deprive him of the honour of a very singular invention."

The italics, *which are not ours*, might well have been at the present juncture. Could it possibly have been the conception purely of a highly imaginative and poetic mind, or had Edgar Allan Poe really learned from a friendly philosopher of the existence of a gas lighter than hydrogen, and whose discoveries may not have reached us for a host of conceivable causes? Perhaps Professor Ramsay or Lord Rayleigh will explain.

INFLUENZA PRECAUTIONS IN MANCHESTER.

JUDGED by the weekly returns of the medical officer of health for the week ending March 23rd—the last which has reached us—the mortality occasioned by influenza appears to be still in the ascendant, the deaths in the week referred to having numbered 33, as against 23 for the previous week. Having regard to the persistence of the malady, Dr. James Niven has, we notice, recently issued a placard setting forth briefly the precautions it is expedient that those attacked and exposed to infection should take. After indicating the symptoms of the disease and referring to its infectivity, Dr. Niven advises workpeople to wear warm clothing and to avoid unnecessary exposure during the prevalence of the disease; and he also points to the importance of paying special attention to the cleanliness and ventilation of factories and workshops, with the view, we presume, of diminishing the risks of infection and promoting recovery. Dr. Niven has done well to issue this notice, and it will do good if only it induces those attacked not to return to work too soon. Unfortunately, we fear many of the workers of Manchester can only partially follow the advice of their medical officer of health; but we trust, for the sake of themselves and those dependent upon them, they will do what they can. If the financial loss to the community of Manchester which the after-effects of influenza have already entailed could be worked out and expressed in figures, it would be a strong inducement to a proper appreciation of Dr. Niven's placard.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

THE appeal issued by the authorities of the Royal Medical Benevolent College in connexion with the approaching festival should come with force to all successful or moderately successful members of the profession. The chair will be taken by the Right Honourable Arthur J. Balfour, M.P. When a statesman of the first rank and with innumerable engagements accepts such a duty, the least that members of the profession whose benefit is contemplated can do is to support him by their presence or their substantial sympathy. A larger subscription is urgently needed to keep up the present annual outlay in charity of £6000. There is a sound of good news for the pensioners of the College. The scheme for improving their condition has received important help from the will of the late Dr. Bowen. The Council hope to be able to raise the annuities of all non-resident pensioners, and that the recipients will be enabled to spend their declining years with their friends. This can only be done, however, in perpetuity by the generous support of the subscribers. The school is open to all classes. The Foundation scholars—fifty in number—receive an education of the highest class and are boarded, clothed, and maintained at the expense of the College. They are elected by the governors from the necessitous orphans o

such medical men as would be eligible for pensionership. Besides these there are about 185 resident pupils. If the sons of medical men, they are charged £60 a year for education, board, &c.; if not, they are charged £70 a year. The introduction of the sons of other than medical men is not only a source of gain and profit to the College, enabling it to do more helpful and benevolent work for the necessitous members of the profession, but it is a distinct advantage to introduce scholars with other callings in view than the medical, and representing other classes. Variety is most desirable. There is the same variety and all-roundness in the teaching. Though science teaching is principally considered, with three laboratories and a lecture theatre, there is a good classical school, where the education is mainly classical, but with a due addition of mathematics, French, German, Latin, natural science, history, geography, and last, though not least, English. The school is recognised by the Conjoint Board as a "school of science," and pupils are prepared for the matriculation examination of the University of London. Special arrangements are made for army candidates, and two boys have recently been prepared for Sandhurst. The ten medical scholarships at the hospital schools in London, ranging from 90 to 125 guineas, and other scholarships or exhibitions at the universities, tend greatly to facilitate the career of any meritorious boy. It will be an inducement to all who are benevolently disposed to give liberally at the approaching festival to know that their donations or subscriptions will go only to the general fund for pensioners or Foundation scholars. We learn that H.R.H. the Prince of Wales has consented to lay the foundation stone of the new buildings contemplated by the council in June.

THE ANTIQUITY OF MAN.

In the current number of the *Nineteenth Century* Professor Prestwich adduces some new facts in support of the great antiquity of man on this planet. The history of opinion on this subject is curious. So recently as 1847 the Geological Society declined to publish a paper which aimed at showing that man co-existed with the extinct quaternary mammalia. Then came the researches of M. Boucher de Perthes, near Abbeville, which proved the existence of human weapons in the quaternary beds containing the fossils of the mammoth, woolly rhinoceros, hyæna, reindeer, &c. Then Professor Prestwich, Sir John Evans, and others showed that undoubted worked flints were present in shingle containing mammalian remains, and so men of science became satisfied that palæolithic man existed in post-glacial times. Here the question rested for a time, but in the course of time inquiry was naturally directed to the problem whether the relics met with in the valley drifts were the work of the earliest race of men. "The workmanship on some specimens of the palæolithic implements was not very much inferior to that of neolithic times, and what was known of the human frame indicated but slight, if any, inferiority in its physical structure to that of modern man. All led one to suppose that ruder ancestors preceded palæolithic man." The most important recent discoveries have been on the North Downs in Kent. Here implements of various kinds—scrapers, drills, hand-picks, roughly chipped flints, &c.—have been found, and Professor Prestwich is disposed to assign a very high antiquity to them. These implements appear to have been used for hammering, for breaking bones, for scraping skins, bones, and sticks, and for chipping and trimming other stones for use. He believes that their age must be assigned to some time previously to, or contemporaneously with, some part of the glacial period. According to Professor Prestwich the appearance of palæolithic man—that is to say, the man of the valley drifts—does not extend probably beyond a

distance of about 20,000 to 30,000 years, and his disappearance at about from 10,000 to 12,000 years, from our own time. Other authorities, such as Croll, have assigned a much more remote period; but while absolute agreement on a matter so difficult is not to be expected, it is evident that geologists are more and more becoming of opinion that a very high antiquity of man is practically certain.

THE MIDWIFE QUESTION.

AN inquest was held on the 3rd ult. at Gainsborough on the body of a woman who had died in childbed, being attended by a midwife until late in the labour, when a medical man was sent for. The patient died from, according to the verdict, "internal rupture." The coroner made the very admirable remark that "midwives were very good when a doctor could not be got, that though in Gainsborough they had every medical facility, still a certain class would persist in employing a midwife, and that the deceased had lost her life simply from not having proper medical attendance."

"GLASS, WITH CARE."

It is noteworthy that serious inconvenience and even injury may result from the most trifling imprudence. A few days ago a barman accidentally fell, broke a bottle he had in his pocket, and received a wound in the leg from the broken glass which caused him to be laid up in hospital. His was a very simple, though an expensive, act of carelessness. Most persons must plead guilty to having repeatedly offended in like manner, and the lesson clearly taught by this accident to all such need not be impressed by further demonstration. For obvious reasons an injury by broken glass is especially troublesome, and it constantly gives rise to subsequent suffering due to retention of broken fragments in the wound. A little forethought in carrying or in handling and opening bottles will usually prevent such awkward consequences of incaution as that above related. Its exercise is the more advisable since bottle glass, even when new, is not guaranteed as free from cracks or other defects.

A NEW ILLUMINANT.

MOST persons have at times noticed a not offensive but peculiarly pungent odour given off from gas stoves in which from insufficient air-supply the combustion is more or less imperfect. This is acetylene, C_2H_2 , a poisonous gas especially fatal to vegetable life. It has hitherto been the practice to estimate the higher hydrocarbons of coal gas in terms of olefiant gas or ethylene, C_2H_4 ; but Professor Vivian Lewes has shown that in the flame they are all resolved into acetylene, and that, having the highest possible percentage of carbon, it is the most powerful of illuminants. Till recently its preparation in the pure state has been difficult and costly, but since it has been found that calcic carbide when slaked evolved this gas, in accordance with the equation $CaC_2 + H_2O = CaO + C_2H_2$, at the rate of over five cubic feet per pound, and that by heating together chalk and carbon of any kind in the electric furnace the carbide is produced at a cost of about £4 per ton, it is proposed to employ acetylene for enriching poor gas either at the works or in the house of the consumer or to burn it in specially constructed lamps. If its poisonous character be understood its strong penetrating odour will be a sufficient safeguard. In this respect it contrasts favourably with carbon monoxide, CO, the most poisonous constituent of coal gas, and a product of incomplete combustion which is quite inodorous. The cost of acetylene would probably be about 7s. per 1000 cubic ft., but its illuminating power is 240 candles, or fifteen times greater than the gas at present supplied to London. Still the tendency to deposition in the

form of soot of the excess of carbon which may possibly escape combustion is an almost insuperable objection to all processes for employing these very high hydrocarbons, and it would perhaps be better to seek "more light" in the direction first pointed out by Drummond in the limelight, and followed by Dr. Auer von Welsbach in his incandescent gas burner, only seeking a less fragile material for the "mantle" than the present form, which is composed of certain rare earths.

PAIN FOLLOWING EXTRACTION OF TEETH.

AT a recent meeting of the Odontological Society of Great Britain a very interesting case of pain following the extraction of a tooth was brought to the notice of the members by Mr. Storer Bennett. The patient, who was a female aged twenty-three, had suffered pain, periostitic in character, from an upper third molar. The tooth was removed without difficulty, but the socket remained intensely painful for the next twelve days, in spite of the repeated applications of such remedies as strong carbolic acid, tincture of aconite, cocaine, and hot poppy fomentations. During this period the socket granulated healthily, except at its apex, where on examination a spot about the size of a pin's head was discovered, which appeared white in colour, and caused on being touched the greatest agony. Thinking that the case was due to the exposure of the end of nerve Mr. Bennett treated it by "division of the nerve just below the surface of the wound." The result was completely satisfactory, the pain ceasing immediately after the operation.

THE NATIONAL LEPROSY FUND.

A SUBCOMMITTEE, consisting of Sir Joseph Fayrer, Sir W. Guyer Hunter, and Mr. Hutchinson, was appointed by the National Leprosy Fund in January, 1894, to conduct such further investigations as to the nature and causes of leprosy as might seem desirable, and it may be remembered that this subcommittee announced in our advertisement columns that they were prepared to offer honoraria of fifty guineas each for the best reports on the following subjects:—(1) On the facts as to the recent increase of leprosy at the Cape and its present prevalence in South Africa; (2) on the history of the decline and final extinction of leprosy as an endemic disease in the British Isles; (3) on the extent to which leprosy prevails in Persia and neighbouring countries, and its supposed causes; (4) on the prevalence of leprosy in the islands of the Pacific, and the supposed exemption of certain groups; (5) on the conditions under which leprosy at present prevails in China, Cochin China, Batavia, and the Malay Peninsula; (6) on the conditions under which leprosy has declined in Iceland, and the extent of its former and present prevalence; (7) on the history of leprosy in Madagascar, and the conditions of its present prevalence; (8) on the reputed recent increase of leprosy on the Australian continent, its extent and possible causes; (9) are there any islands in the East Indian seas wholly free from leprosy, and, if so, in what do their conditions differ from those in which it prevails? (10) the best essay on any subject connected with leprosy (the honorarium for this essay was, if the committee thought fit, to be added to any of the preceding). We have received from the subcommittee and adjudicators of the awards the names of the gentlemen who have gained prizes in the different subjects, and they are as follows:—On the Facts as to the Recent Increase of Leprosy at the Cape and its Present Prevalence in South Africa: S. P. Impey, M.D., Medical Superintendent, Robbin Island. On the History of the Decline and Final Extinction of Leprosy as an Endemic Disease in the British Islands: George Newman, M.D. On the Conditions under which Leprosy has declined

in Iceland and on the Extent of its Former and Present Prevalence: Edward Ehlers, M.D., of Copenhagen. On the Reputed Recent Increase of Leprosy on the Australian Continent; its Extent and Possible Causes: Ashburton Thompson, M.D. On the Conditions under which Leprosy prevails in China, Cochin China, Batavia, and the Malay Peninsula: James Cantlie, M.B., of Hong-Kong. On some of the subjects for which prizes were offered no essays have been received. Some of those which were sent were not considered by the subcommittee to be sufficiently full to meet the terms of the competition. We are asked to announce that unsuccessful authors can have their manuscripts returned on application at 1, Park-crescent, Regent's-park.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE trustees of the will of the late Mr. William A. Guesdon have informed the Lord Mayor of London that in pursuance of the powers vested in them by the will they have chosen certain charitable institutions to participate in the estate generally. Under the scheme it is understood that a sum of £45,346 1s. 3d. in Consols is to be transferred into the names of the Official Trustees of Charitable Funds, who will remit the dividends on the Consols to the Lord Mayor of London for the time being, in trust for the Hospital Sunday Fund. We congratulate the Council of the Fund on this handsome augmentation of their income, and trust that it may be a long time before the trustees in whom the discretion is vested will find a charity more worthy of their assistance. The interest on a further sum of £9069 4s. 3d. has been left to the Mansion House Poor-box.

THE CONFERENCE ON SANITARY PROGRESS AND REFORM AT MANCHESTER.

THE annual meeting of the Manchester and Salford Sanitary Association on April 24th will inaugurate a conference to extend over three days. It is promoted by the association in connexion with the district councils for the registration of plumbers in the northern and midland counties. The former will occupy the Wednesday and Thursday, and the latter part of Thursday and Friday. The subjects to be chiefly dealt with in the first part of the Conference are Air Pollution, Sanitation of Schools, Recreation—both Physical and Mental, and Woman's Work in Sanitary Reform. Addresses and papers are promised by Sir R. Rawlinson, Sir B. W. Richardson, Cardinal Vaughan, Lord Meath, Mr. Charles Roberts, and others. An International Health Exhibition is to be held in St. James's Hall, which will open on April 22nd and close on May 11th. It is under distinguished patronage and will be on an extensive scale.

THE MODERN TRAINED NURSE.

SIR DYCE DUCKWORTH has always taken a deep interest in nursing and in the Royal British Nurses Association, of which he is vice-president, and in an address delivered before this body the other day he laid stress upon various important points connected with the profession of nursing, and not the least of these was the absolute necessity, as he pointed out, of a nurse being subservient to the medical man. The old style of nurse has so entirely disappeared that the patients and practitioners of this generation can hardly realise how much the successful treatment of disease owes to the help of an intelligent, trained woman; and this expression, *trained*, means, as Sir Dyce Duckworth clearly pointed out, not only medical and physical knowledge, but tact and silence. The abbot of a Nitrian monastery once gave one of his monks as a rule of life the first verse of the psalm commencing, "I said I will take heed to my ways, that I offend not with my tongue." "When you can keep that rule," he said, "come, and I will give you another." Tradition has it

that the worthy monk never arrived at the second. Be this true or not, it shows how the tongue in all ages has been regarded as an unruly member, and all nurses ought to remember to be absolutely silent as regards anything they may see or hear outside their own immediate duties. The Hippocratic oath still remains the canon for every attendant on the sick, either nurse or medical practitioner, and on this point Sir Dyce Duckworth rightly spoke with great earnestness.

LORD ROSEBERY'S HEALTH.

WE had hoped to be able to announce that the Premier was now entirely restored to his usual health. Unfortunately, however, his recovery is not yet quite complete, although he is making good progress. It is chiefly owing to want of sufficient sleep that his convalescence is retarded. Lord Rosebery is able to take riding and walking exercise daily—a fact of good import, as there can be no better remedy for insomnia than healthily acquired fatigue.

THE ISOLATION HOSPITAL ACT IN WORCESTERSHIRE.

THE Worcestershire county council, to which Mr. George Frobroke is medical officer of health, has exhibited considerable activity in the matter of joint hospital districts, and two such districts have recently been formed. In both instances one or more of the constituent authorities petitioned the county council, under the provisions of the above Act, that certain joint hospital districts should be constituted, and in each case an inquiry was subsequently made under Section 6 of the Act by the county medical officer of health. The council considered a *prima-facie* case made out and, after local inquiry as provided for by the Act had been held, the Bromsgrove, Droitwich, and Redditch, and the Malvern hospital districts were established. A hospital committee has in each case been provided for by the order, and such committees are possessed of extensive powers as regards management &c. They have, however, no power to raise money by loan for the purposes of a hospital. Such powers would appear to be alone possessed by the county council, who, with the consent of the Local Government Board, are, by the Local Government Act, 1888, empowered to borrow for the purpose indicated. It seems, too, that under the Isolation Hospitals Act, 1893, any money so borrowed must be repaid to the county council by the local authorities with interest at the rate of 4 per cent. We shall look forward to the further development of affairs in connexion with these two districts, and we note with pleasure that in the Malvern district provision is already made for a separate small-pox hospital. The committee in each instance is composed of representatives from the local areas concerned, and the county council have no representation upon them.

UNHEALTHY AREAS IN LEEDS.

LIKE most large cities, Leeds suffers to-day from the ignorance or indifference of our forefathers in "the good old times" as to the conditions necessary for healthy town life, in being compelled to spend large sums of the ratepayers' money in order to remedy ancient blunders. The sanitary committee has just obtained the sanction of the Council for the preparation of a scheme for dealing with one notoriously unhealthy district of seventy-seven acres. This is a large undertaking, and the medical officer of health, Dr. Cameron, is to be congratulated on his courage in attacking sanitary evils so boldly, and in being so loyally supported by his committee and by the Council. The district has long been known as "a standing menace to the health of the city." Forty years ago typhus fever constantly prevailed, but the people objected to inter-

ference by the sanitary authority, so that "the aid of a posse of police had to be sought when typhus fever patients were removed to hospital." And its old reputation has been well kept up, for the death-rate is 30 per cent. more than the average of the city, including this area, notwithstanding many attempts to improve its sanitary condition. It is proposed to open out the district by running through it certain main roads, which will be a great public convenience; to alter certain levels and steep gradients; to pull down and demolish bad property, but to leave standing large works and public buildings. The cost is roughly estimated to be between £300,000 and £400,000. The sale of the cleared land is expected to bring in a good round sum. The scheme proposed divides the area into five sections, to be dealt with separately and not all at once. In the discussion on the question one gentleman said, "What about the Leylands? There was not a dirtier place in Leeds; people slept in the cellars there and yet did not die." This weighty argument did not prove effective, for in the end the resolution of the sanitary committee was carried by 47 to 5. On the question of rents one speaker said: "The Corporation had the power to build back-to-back houses, which could be erected and let at a minimum rent." If this power is acted on it will be a notable instance of retrograde progression which Leeds will surely not take.

THE ETIOLOGY OF LOCOMOTOR ATAXY.

DR. PITRES of Bordeaux has made extensive investigations in the hope of throwing light upon the still doubtful points in the etiology of this disease. His first results were published in a thesis by Dr. Bereni and comprised 225 cases. The influence of syphilis was found to be great but not overwhelming, and was by no means in keeping with recent ideas on the subject. In considering those cases in which the etiology was certain there were 125 out of 225—i.e., 55.5 per cent.—and even in many of these cases the syphilis was associated with other causes of tabes dorsalis as hereditary joint affections, alcoholism, sexual excess, &c., so that the exact percentage which could safely be attributed to syphilis was reduced to 22.33 per cent. Of the other patients about 33.44 per cent. had no sign of previous syphilis, and twice during his experience Dr. Pitres has seen tabetic symptoms precede syphilitic manifestations, so that these statistics tend to show that though syphilis is a cause it is not by any means the only one, but that many other conditions also play their part in setting up the disease. There is also in Dr. Bereni's work a chapter on the investigation of the heredity of tabes, but no direct tendency to inheritance was found.

TRAINED NURSES AT A WORKHOUSE.

SINCE the issue of the circular from the Local Government Board at the beginning of the year upon workhouse administration, in which special stress was laid upon the absolute necessity of supplying good nurses, numerous boards of guardians, at any rate in Sussex, at once gave the matter their attention. A board in South-west Sussex appointed a head nurse and two assistants, but the time they did duty at the workhouse was so short as to be able to be counted by the hours. At the first meeting of the board after the arrival of the nurses the master stated: "They defy the authority of the master and the matron, and find fault with everything, in short." An important point, it appeared, was that the nurses refused to bath the vagrants. In that the nurses were workhouse nurses, the guardians considered that this was part of their duty, but the head nurse held quite a different opinion, and one in which the medical officer concurred. So short a time had the nurses been in the workhouse that their appointment had not been confirmed, and by mutual consent they

remained but a very hours in the service of the guardians after their meeting. It was admitted by more than one member of the board that the nurses had been the means of discovering many imperfections which otherwise, perhaps, for some time to come would have continued to remain dormant—one beneficial result of the Local Government Board's circular. It is needless to add that the whole matter is to receive the full consideration of the guardians, and we hope means will speedily be adopted whereby such a state of things which has existed in the workhouse in question will entirely disappear.

THE Radcliffe Travelling Fellowship at Oxford has been gained by Mr. Arthur C. Latham, M.A., M.B., Ch.B., of Balliol College. Mr. Latham graduated as a First Class in the Final Natural Science Schools in Physiology in 1892 and a Second Class in the Final Natural Science School in Chemistry in 1890. He obtained a University Scholarship at St. George's Hospital, London, 1893, open to students of Oxford or Cambridge. Mr. Latham is a son of Dr. P. W. Latham, the late Downing Professor of Medicine in the University of Cambridge and the present Senior Censor of the Royal College of Physicians of London.

MR. H. J. WARING, M.S., M.B., B.Sc., F.R.C.S., of St. Bartholomew's Hospital, has been awarded the Jacksonian Prize of the Royal College of Surgeons of England. The exact title of his Jacksonian Essay is "The Diagnosis and Surgical Treatment of the Diseases of the Liver, Gall-bladder, and Biliary Ducts." Mr. Waring holds the appointments of Senior Demonstrator of Anatomy, and Demonstrator of Operative Surgery, at St. Bartholomew's Hospital; and Assistant Surgeon to the Metropolitan Hospital.

In another column will be found a report of the first day's proceedings of the German Congress of Internal Medicine, which has been taking place this week at Munich under the presidency of Professor von Ziemssen. The discussion upon the Antitoxin Treatment of Diphtheria was one of great importance and had been anticipated with interest.

SIR JOSEPH LISTER was received by the Prince of Wales at Marlborough House on April 9th, and was presented by His Royal Highness with the Albert medal of the Society of Arts, which had been awarded to him in recognition of his application of antiseptic methods to practical surgery.

THE Festival Dinner of the Royal Medical Benevolent College will be held at the Queen's Hall, Langham-place, on Wednesday, May 15th. The Right Honourable Arthur J. Balfour, M.P., will take the chair.

THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1893.

(Concluded from p. 828.)

WITH regard to the prevalence of enteric fever—that scourge of our European troops serving in India—the returns for 1893 show that there has been a slight decrease in admissions and deaths. The improvement, we are told, is hardly appreciable, however, in Bengal and Madras, but more marked in the Bombay Presidency. At Sialkot, Agra, Meerut, Lucknow, Bareilly, Umballa, Rawal Pindi, and some other stations the disease was specially prevalent, the admission-rate ranging from 49.3 at Sialkot to 21.7 per 1000 at Bareilly.

At Agra, where the admission-rate was 42.6 and the death-rate 12.43, there was a circumscribed outbreak in the East Surrey Regiment, in which no less than 42 occurred out of a total of 48 cases in the garrison. Mr. Hankin, the chemical examiner and bacteriologist for the North-West Provinces, found, it will be remembered, typhoid bacilli in the aerated water and in the *dahi* (eaten in the shape of cream, cheese, or sweetmeat) supplied to the regiment. As regards the greater liability of the young soldier recently arrived in India to be attacked with this fever there can be no doubt. It is a matter which has been already threshed out, and the evidence in the present is but a repetition of that in former reports. A comparison of the relative liability of European troops, native troops, and gaol population to enteric fever shows its very unequal incidence upon Europeans and natives in India.

	Per 1000.			
	1882-1891.		1893.	
	Admissions.	Deaths.	Admissions.	Deaths.
European troops	14.7	4.13	20.0	5.29
Native troops	0.3	0.09	0.3	0.04
Gaol population	0.2	0.10	0.3	0.16

From some of the descriptions recorded of the post-mortem appearances in natives it is not clear that they were all really cases of enteric fever. The Goorkha regiments seem, on the whole, to be more liable than other native troops to this disease—a fact which possesses some interest. Our knowledge of the etiology, causes, and pathology of enteric fever in India cannot be said to have been greatly advanced of late. Assuming that the disease depends upon the Eberth-Gaffky bacillus, the question narrows itself into an investigation into the life-history of that bacillus and the way in which it finds an entrance into the human body. It seems clear that ordinary domestic filters are incapable of removing pathogenic microbes from water. The barrack filters at present in use in India apparently afford little or no protection to the troops; indeed, it is questionable, as we have said, whether they are not sources of danger. We repeat that every care should be taken to secure a good and pure water-supply at its source and to keep it free from all contamination. The Pasteur-Chamberland or Berkefeld filters should, we think, replace the filters ordinarily used in India. It might be very advisable, too, if some economical and easy method of destroying typhoid excreta by fire could be adopted. Some observers entertain the view that all the cases of enteric fever encountered in India, although clinically and pathologically allied to that fever in other countries, are either not necessarily identical with it in causation or, assuming that they are all of the same nature and attributable to one and the same specific cause, that the generation and reproduction of this cause do not take place exclusively in the human body. Be all this as it may, however, it is clearly our duty to search out and remove those causes which have been already established. Although the part which sewer air, for example, may play in its production may be still open to doubt, and in the case of India there are no sewers except in some of the cities and large towns, the evidence that has been adduced in regard to contaminated water and milk as causes of this fever does not seem to admit of any doubt. The difficulty in regard to some outbreaks in India is to explain on this theory the relative or absolute immunity of children and women on such occasions.

The amount of inefficiency in the European army in India attributable to venereal diseases is, we may almost say, appalling, especially when we consider the impaired health and subsequent constitutional effects of syphilitic infection. During 1893 there were, we are told, 2619 men, or the strength of nearly three regiments, constantly in hospital for venereal diseases.

The report under review has, as usual, an interesting table showing the results of a tour of Indian service upon European corps. Out of 872 men in one regiment who came to India sixteen years before only 8 returned with it: 66 had died, 114 had been invalided, 8 returned to England, and the remainder had been transferred to other regiments or discharged from the service.

The proportion of married to unmarried soldiers in India is 2364 of the former to 69,422 of the latter; in other words, the percentage of married to total strength is 3.29. The statistics regarding the women show a great improvement in 1893 in respect of admission and death-rates upon those of 1892, which were unusually high. The chief causes of death among soldiers' wives were enteric fever, puerperal fever, childbirth, and remittent fever. In the Bengal Presidency the death-rate was 16.26 per 1000, in Madras 7.66, and in Bombay 15.85.

The children of the army in India, amounting to a strength of 5662, had an admission-rate of 554.9 and a death-rate of 39.03 per 1000 respectively in 1893. There were no deaths recorded from cholera, and only 4 from enteric fever, the ages of the children ranging from infancy to fifteen years and upwards.

There were 6382 officers on the strength of the army in India on July 1st, 1893. The death-rate of officers of the British service was 10.67 per 1000, and of the Indian service 8.82; the difference is due to the larger number of deaths from enteric fever among the former, the respective numbers being 11 and 1, and the explanation of the difference, we are informed, and no doubt correctly, is probably due to the fact that officers do not join the Indian service until they have served for a year or two with a British regiment in India.

As regards the native army of India its average strength was 127,091. The year 1893 is stated to have been one of the most healthy in its history. The cholera mortality was the lowest on record. The admission-rate was 862, the deaths from cholera were 0.20, from all causes 10.29, and including absent deaths 12.81 per 1000 respectively. The chief causes of death were pneumonia and other respiratory diseases, remittent and intermittent fevers. Pneumonia caused 33 per cent. of the total mortality, and other respiratory diseases 13 per cent. It is pointed out in the report that a comparison of the diseases of the native troops and those of Europeans shows how much less the former suffered from enteric fever, heat-stroke, and venereal diseases, while, on the other hand, the Europeans suffered less from influenza, pneumonia and other respiratory diseases, dysentery, and scurvy. While the admission ratio for venereal diseases in the European army in 1893 was 466 per 1000, it was only 36.4 per 1000 among native troops. Many causes may be assigned for this great difference; for instance, the restraining influence of caste, the temperate habits, smaller pay, and frugality of the native soldier.

We pass over that section of the report dealing with the galls of India and come to that of the vital statistics of the general population. As regards the principal diseases which contributed to the mortality of 1893, we find that cholera was less prevalent than in 1892 with the single exception of Assam; small-pox was also less prevalent; the fever mortality in Berar, Lower Burma, and Mysore somewhat greater; and dysentery and diarrhoea prevailed with greater severity only in Berar. The fall in cholera prevalence and mortality was general in almost every Indian province. The number of deaths from cholera fell from 762,695 in 1892 to 218,113 in 1893. In the Punjab the decline was from 76,000 to 639, in the Central Provinces from 40,000 to 557, and in Rajputana from nearly 27,000 to 314. Nothing serves to mark the marvellous difference between an epidemic and a non-epidemic cholera year better than figures of this sort. The great and abiding cause of mortality among the native population of India is fever, or what is returned as such. The total mortality from this cause is so enormous that it dwarfs that from all other causes.

There is an important memorandum, illustrated by a diagrammatic map, on the influence of railways in the dissemination of cholera, by Surgeon-Major J. Lewtas, M.D., officiating statistical officer to the Government of India in the sanitary and medical departments. He finds, as the result of a very careful and elaborate inquiry, that there is no ground for such a belief. Cholera is not more frequently manifested or more rapidly carried about from place to place than it was in pre-railway days, nor does cholera follow the lines of railway. If railways were the means of disseminating cholera they would obviously carry it in any direction indifferently, which they do not. Of course, cases of cholera may be thus carried, but they do not seem to have any influence on the course of an epidemic. In the Bengal Presidency the direction of an epidemic is always upwards—towards the north-west frontier; an epidemic moving downwards is unknown.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE extraordinary meeting of the Fellows for the purpose of the annual election of President was held on the 8th inst. The President, Sir J. Russell Reynolds, opened the proceedings by a few well-chosen remarks of sympathy at the loss sustained by the profession and the Royal College of Surgeons of England in the death of Mr. J. Whitaker Hulke, whose sterling characteristics he admirably sketched. The President then proceeded to deliver his annual address. The College roll now contained the names of 303 Fellows, 497 Members, 5 Licentiates prior to 1859, 12 extra-Licentiates, and 5970 Licentiates. Six Fellows had died during the past year—viz., Drs. Brown-Séquard, Little, Sturges, Withers Moore, Bisset Hawkins, and Hack Tuke. Mention was made of the inspection of the examinations by the General Medical Council and of matters of finance, the latter including the attempt of the Inland Revenue to make the College amenable to the Corporation Duty (1885), from which the College claimed exemption in consideration of its function as an educational body. The claim was under consideration, but would be pressed further, if necessary. In referring to the award of the Moxon Medal to Sir W. Jenner, the President observed that it was a remarkable circumstance that this medal, founded in honour of one of the most distinguished Fellows, should have been awarded to two physicians of whom he was young enough to have been the pupil—viz., Sir A. Garrod and Sir W. Jenner. The acquisition of the portrait of Sir A. Clark, painted by Mr. R. Lehmann, was referred to, and the munificent foundation of the Weber-Parkes Prize and Medals by Dr. Hermann Weber suitably acknowledged, as also was the gift of the Goldsmiths' Company to further researches on the antitoxin treatment of diphtheria. The lectures delivered at the College during the past year were enumerated, and the work of the Committee on the Nomenclature of Diseases stated to be far advanced. As regards the University of London, the President said that there was good reason to hope that the subject of the appointment of a Statutory Commission would be brought into the House of Lords after Easter. The conferment of a knighthood upon Dr. J. C. Bucknill, and of baronetcies upon Dr. John Williams and Dr. Russell Reynolds, was also mentioned. The President then proceeded to give obituary sketches of the deceased Fellows, and of Dr. Greenhill, a distinguished Member of the College who had declined the Fellowship when offered to him. At the close of the address a vote of thanks to the President was unanimously adopted on the motion of Sir R. Quain, seconded by Sir Dyce Duckworth.

The election of President was then taken, when it was found that Sir J. Russell Reynolds had received 76 votes, Dr. Wilks 2, Dr. Bastian 1, and Sir A. Garrod 1, there being eighty-one Fellows present and eighty voting.

Sir J. Russell Reynolds was then inducted into office by the Senior Censor (Dr. Latham) and having made the declaration returned thanks to the Fellows for having chosen him for the third time to preside over the College.

On the motion of the Treasurer, seconded by the Senior Censor, it was resolved that the College undertake the expenses attending the publication of the biography of Sir Henry Halford, formerly President of the College, which had been prepared by Dr. Munk, the librarian.

Communications were read from the Royal College of Surgeons of England relative to the representation of the Royal College of Physicians at the memorial service held at St. James's Church, Piccadilly, on the occasion of the funeral of the late Mr. Hulke; and also a letter from Mr. Wilmott, on behalf of Mrs. Hulke, expressing her sense of the sympathy shown by the College in her bereavement.

Dr. Henry de Fomartin having resigned his Membership on account of his undertaking practice at Montpellier under conditions which would require him to dispense medicines, the resignation was accepted by the College.

The alteration in By-laws CLXII. and CLXIII. was moved for the second time by the Registrar and adopted.

A report from the Committee of Management embodying the substance of a reply to the report of the Inspector of the General Medical Council upon the examination for the diploma of Public Health was received. Dr. Heron moved that the

report be referred back to the committee for re-consideration and amendment. The motion was seconded by Dr. Thorne Thorne and the discussion upon it shared in by Sir Dyce Duckworth, Dr. Stevenson, and Dr. Norman Moore. Dr. Heron's amendment was carried by 20 votes to 12.

A supplementary report from the Committee of Management, recommending that Mr. Thomas Cooke's Course of Operative Surgery be recognised as fulfilling the requirements of the Regulations for the present year on the same conditions as heretofore, was adopted, and the Comitia adjourned.

THE HEALTH OF THE ITALIAN ARMY.

To the *Ispettorato di Sanità Militare* our thanks are due for a report on the health of the Italian army in 1893—a report which may be described as more than ever satisfactory, the improvement registered in 1892 being more than maintained.

The admissions into hospital for 1893 were 80,208—a figure which includes 11,468 whose admission was renewed for "continuazione di cura"; so that, these being deducted, the number of troops on the sick list was really 68,744.

Those admitted into the military hospitals, the garrison infirmaries, and the special infirmaries were 78,132, of whom 2336 came from other hospitals. The number, therefore, of admissions from the corps shrinks to 75,796, comprising 104 accommodated in canvas casual quarters, and 6708 admitted "in osservazione."

The admissions into convalescent quarters were 1733, of whom 1629 had been transferred thither from the hospitals and 104 contributed by the corps.

In the civil hospitals the admissions of troops amounted to 13,032, besides 59 coming from the other hospitals. Among them were 88 who had to be accommodated in divers lunatic asylums, as well for cure as to be kept under surveillance ("in osservazione").

The greatest absolute number of troops admitted into the civil hospitals was in the division of Leghorn—a priority, however, which proportionally to the respective mean force, belongs to the division of Perugia. The smallest number of admissions under this head is contributed by Turin.

The greatest contingent of patients came from the field artillery; next in order come the infantry of the line, the cavalry, "i distretti" (district service), the artillery in forts, the engineers, and the "bersaglieri." The smallest contingent was that of the carabinieri. As a whole, the mean proportion of disease and of days under treatment in 1893 was lower than that of the preceding quadriennium.

With regard to the months in which the number of soldiers on the sick list was greatest the minimum was reached in February and the maximum in March and April; in May the increase began again to diminish, and continued in that direction, save in July, when a slight rise was noticed, due to the greater fatigue of the soldiers in the summer exercises. The minimum of disease was in November. The mortality also was at its highest in April and at its lowest in February.

The accentuation of disease in March and April, with the consequent exceptional mortality, is due to the arrival of the recruits, who in the first month of their service give always a large contingent of invalids. From the report, however, we gather that on the whole in 1893 the sanitary conditions of the army were in all respects better than throughout the whole preceding quadriennium.

The military divisions, taken singly, presented no slight difference in the mean proportions of the patients admitted, of the dead, and of the "riformati" (those dismissed the service for illness), per 1000 of the respective mean force. Taking the statistics of the last five years, we gather that the mean of sickness in all the years was exceeded in the divisions of Perugia, Rome, Naples, and Bari; that it was never attained in the divisions of Turin, Milan, Brescia, and Genoa; that in 1893 that mean was exceeded in the divisions of Ancona, Chieti, Rome (Sardinia), Perugia, Naples, Bari, Catanzaro, and Messina; and that all the other divisions remained "disotto" (under). The maximum of sickness was still maintained by the division of Perugia, and the minimum by that of Genoa.

As to the different arms of the service, the greatest contingent of maladies belongs to the infantry, after which comes the fort artillery ("artiglieria da fortezza"), while for surgical operations the cavalry and field artillery had the pre-

eminence. The cavalry also had the greatest number of eye diseases. For venereal diseases the most prominent were the foraging companies ("compagnie di sussistenza"), the artisan companies of the artillery, and the engineers. The minimum was presented by the Alpine corps.

In 1893 the maladies of the respiratory organs were under the average (except in the case of pneumonia); as were also enteric fever, measles, most fevers and cachexia, influenza, articular rheumatism, and venereal and syphilitic ailments. An augmentation, however, was shown in scarlet fever, infective cerebro-spinal meningitis, with the addition of some cases of Asiatic cholera, this latter being wholly absent in 1892. Infective cerebro-spinal meningitis appeared with the arrival of the recruits of the various corps.

The number of deaths among the troops during 1893 was 1412, or in the proportion of 6.6 per 1000 of the mean force; hence again a diminution of 7.1 per 1000.

Mortality above the collective average was shown by the sanitary companies, the "distretti," the cavalry, and the royal carabinieri; the same mean was not reached by the foraging companies, the Alpine corps, the "bersaglieri," the artillery, the engineers, and the military penal establishments. The maximum was found in the sanitary companies, the minimum in the foraging companies. The mortality in 1893 was below the average in the infantry, the "bersaglieri," the cavalry, the artillery, the engineers, and the military penal establishments, and above it in the other corps.

In 1893 for every month there was a lower mortality than that of 1892, except for March, April, July, and October. April furnished the greatest number of deaths, February the least. The greater mortality of April was caused by the arrival of the recruits called in March.

In the military divisions the mean of the mortality was exceeded in the divisions of Alessandria, Cuneo, Brescia, Piacenza, Genoa, Ancona, Chieti, Rome, Perugia, Salerno, Bari, and Palermo. In all the other divisions, including the island of Sardinia, the mortality was below the mean. The maximum death-rate was reached by the division of Bari, and the minimum by that of Ravenna.

"POST-INFLUENZAL MENINGITIS."

BY T. C. MAXIME,

OF THE FACULTÉ DE MÉDECINE, LYONS.

It may be of interest to the readers of THE LANCET if I give a brief account of "post-influenzal meningitis," upon which Dr. Roque, Chef de Clinique to Professor Boudet of the Hôtel Dieu, Lyons, gave a learned exposition on March 19th. The subject is one which has been much discussed and reported upon of late by medical authorities, both in Paris and Berlin; but it is not a new point in post-influenzal affections, at any rate at Lyons, where it has been studied and described since 1839. In meningitis following influenza, which is rarely fatal, death hardly ever resulting from the influençal affection itself, there is no lesion whatever to be found at the necropsy either in the brain or medulla. The affection is carried by the special action of the toxines secreted by the influençal microbes producing inhibition phenomena, toxines which appear to have a very special predilection for the nerve centres.

Sometimes, though the event is rare, in cases of patients dying from meningitis which has supervened on influenza suppurating lesions of the brain and meninges are found, but these cases are not instances of post-influenzal meningitis strictly so called; it is rather a secondary affection brought out by influenza—a true meningitis preceded by influenza, and due to a streptococcus, staphylococcus, Koch's bacillus, or more often to the pneumococcus. But these cases of suppurative meningitis succeeding influenza are very rare, for out of the records of thousands of cases collated by Dr. Roque from various sources, there are only eleven deaths due to this sequel to "la grippe." Other cases belong to the category of post-influenzal meningitis strictly so called, which have a gravity of their own, symptoms quite similar to those of true meningitis, but none the less essentially very benign in nature, the brain not being injured by the progress of the malady itself. (It might have been damaged previously). Dr. Roque was induced to again put forth his views by the occurrence of a case under his care which unfortunately proved fatal, and in which a necropsy

was made. "This patient was admitted into the Hôtel Dieu a short time ago for influenza, having no special features and running a mild course, so that only the routine treatment was prescribed and no exceptional notice was taken of the case. But one day the patient was attacked with intermittent delirium, shortly afterwards becoming almost continuous, which together with other special symptoms attracted particular attention. Careful examination showed paralysis of the external recti muscles of the eyeballs, and very acute pains in the head, especially in the frontal region. Then the palsy involved the other recti. The patient had vomiting of cerebral origin, rigidity, retraction of the head, tenderness over the nuchal muscles, violent excitement requiring restraint at times, and, in a word, all the phenomena of meningitis; but it was remarkable that in spite of all this there was no marked rise of temperature, which ranged from 38° to 39° C. Suitable treatment was adopted and a favourable issue was foreseen, the condition, indeed, beginning to improve, when the patient's temperature suddenly rose and death ensued. One hardly knew what to think of this anomalous fact, and the necropsy was carefully made. Now although this patient had presented all the symptoms of meningitis there was absolutely no lesion found in the brain, no special change of any kind although several sections were made. Yet if, as stated above, post-influenzal meningitis be a very benign affection, why did this patient die, especially in this anomalous manner? The explanation is simple; it was because he had been attacked with a secondary cardiac affection, for the right auricle was found to be filled with a firm coagulum sending prolongations into the vessels and ventricle."

To sum up, post-influenzal meningitis is a benign affection which advances with violence, but which has not actually ever any serious issue. The meninges are not in the least injured, and the affection is brought about by the special action on the meninges of the toxins secreted by the influenza microbes, and not by the microbes themselves; toxins for which the cerebro-spinal fluid probably serves as a receptacle, just as this fluid is one of the best culture media for microbes in local disease. This wholly peculiar action of the toxins of the influenza microbes is, moreover, confirmed by the fact that the subjects of influenza who do not have post-influenzal meningitis do not escape presenting very marked symptoms of prostration, hypochondriasis, and depression (lasting a month or so)—phenomena which may be regarded as highly attenuated forms of the action on the nerve centres produced by the toxins.

Lyons.

THE CONGRESS OF MEDICINE IN MUNICH.

THE DEBATE ON THE ANTITOXIN TREATMENT OF DIPHTHERIA.

THIS Congress, which was opened on April 2nd, was attended by a great many leading medical men. The chair was taken by Professor Ziemssen of Munich. In his presidential address the chairman said that in his opinion at no period of the history of medicine were there such zeal and assiduity as at the present time. Undoubtedly progress in medical science depends mainly on the quiet work in hospital wards, in dissecting-rooms, and in laboratories; but periodical meetings enable the representatives of the different branches of medicine to compare their results and to know each other's views. It had always been, and he hoped always would be, the principle of this Congress to consider medicine as a unity, and therefore to maintain the connexion of internal medicine with surgery and pharmacology. The principal task of science was *rerum cognoscere causas*. Medicine had passed through the periods of anatomical and pathological research, and now had arrived at the era of etiology. We now try first to learn the causes of the different illnesses, and then to base the treatment on this knowledge. The antitoxin method, which would be the principal theme of this year's meeting, was a good specimen of the new era in the art of curing, as it was really founded on etiological examinations.

Baron von Feilitzsch, the Prime Minister of Bavaria, then welcomed the Congress in the name of the Government, the Mayor Brunner in the name of the city of Munich, and Professor Beyer on behalf of the University. Prince Ludwig Ferdinand of Bavaria (who is himself a medical man) was elected honorary president, and Professor Wiederhofer

(Vienna), Professor Bollinger (Munich), and Professor Leyden (Berlin) vice-presidents. Dr. Hochhaus (Kiel), Dr. Klemperer (Strasburg), and Dr. Sittmann (Munich) acted as secretaries. After these introductory proceedings the Congress began its work by a debate on the Antitoxin Treatment of Diphtheria, Professor Heubner delivering the first address.

Professor Heubner declared himself persuaded that a new epoch dated from Behring's invention. There was no doubt that Bretonneau's diphtheria was influenced by the remedy. Although he fully appreciated the difficulty of judging medical questions by the means of statistics, he pointed out that the mortality of diphtheria in Berlin had fallen from 44 per cent. to 21 per cent. The same fact was remarked wherever the remedy was used. It was, therefore, quite impossible for him to believe that this lowering of mortality was due to a weakness of the "genius epidemicus." In his statistics he had, of course, only reckoned the cases which were characterised as real diphtheria by the presence of Löffler's bacillus. All the other cases of diphtheria-like disease where this bacillus was not found he proposed to term "diphtheroid." The following effects of antitoxin could be noted:—1. That it has an influence on the course of the temperature; in diphtheria there is generally an access of fever after a few days of normal temperature. In antitoxin cases this has rarely ever happened. 2. That the pseudo-membranes are more easily loosened. 3. That the progression of the diphtheritic infiltration is stopped. The larynx can be kept free by early injections; but in cases where the larynx was already attacked the antitoxin did not prevent laryngo-stenosis. 4. That the intubation tube can be removed in a much shorter time. An absolute reduction in the number of albuminuric cases was not stated, but it was remarkable that the greater part of those patients who were injected on the first day remained free from albuminuria. The paralysis and the cardiac debility were not influenced by the remedy. The immunising effect was not at all sure and seemed to last only for a few weeks; the doses proposed by Dr. Behring appeared to be much too small for this purpose. Of complications Professor Heubner mentioned the angelo-neurotic eruptions as caused by the serum; they did partly produce rather disagreeable symptoms. That the antitoxin could bring about nephritis was not all proved. He finally repeated his opinion that only a very early commencement of the treatment would give favourable results.

Professor Baginsky (Berlin) reported 525 injected cases. Whilst the average mortality of the illness in Berlin was 41 per cent., the antitoxin cases had only a death-rate of 15 per cent. In August and September, when the supply of serum failed, it rose again to 51 per cent. He had observed a great amelioration of the patient's general state, which, however, was only remarked on the second or third day after the injection, and a lowering of the temperature. In many cases he had seen a sudden stopping of the local affection; as in Professor Heubner's cases, the larynx, if not yet attacked, remained free; intubation could be performed with more success, so that tracheotomy could nearly totally be done away with. Sudden death from cardiac debility was very rare, and myocarditis was seldom found by post-mortem examination. The serum had no bad effect on the kidneys, nor was phenol present in the urine. It appears that carbolic acid, if combined with antitoxin, offers no phenolic reaction. Paralysis was, however, more frequent than before, maybe because more children remain alive. Sometimes suppuration at the place of the injection was observed, principally when the latter was made, not under the skin, but into the muscular substance. The rashes are not of great importance, and in diphtheria had occurred before the new method was used. He warmly recommended a continuance of the antitoxin treatment.

Professor Wiederhofer (Vienna) expressed the same opinion as Professor Heubner and Professor Baginsky.

Professor von Ranke (Munich) said that all his cases were of three or four days standing when treatment was commenced. Of 96 patients, 63 had still laryngo-stenotic symptoms. In 21 of those 63 cases laryngo-stenosis very soon disappeared; in 42 intubation was performed; of these 13 died. The intubation period was much shorter than before. He thought that the antitoxin was able to prevent the diphtheritic process from descending to the larynx and the lungs.

Dr. Kohts (Strasburg) said he had not seen very marked benefit, some cases excepted, where the local affection seemed to disappear more quickly than before.

Dr. Grawitz (Berlin) reported his experiments of *intravenous* injection of blood serum on rabbits and dogs. He had observed an extreme dilution of the blood, caused by the attraction of water from the tissues and the raising of the secretion of the kidneys. The *subcutaneous* injection of blood serum had the same effect. Patients who had been treated with antitoxin also showed an increase of water in the blood. After ten or twelve hours this hydremic state passed away and was followed by a decrease of the quantity of water. Dr. Grawitz concludes from these facts that it was still an open question whether the action of the antitoxin depends only on the increase of succulence in the tissues or is a really antitoxic one.

Dr. Seitz (Munich) had had the same good results as Professor Heubner and others. He alluded to the alleged injurious effects of the serum and denied them to be of any importance. Like other observers, he had remarked an increase of the exanthemata, whether the serum was only prophylactically used or used as a cure.

Dr. Stintzing (Jena) was of quite a different opinion from the greater part of the physicians present. He warned the meeting to be very reserved in its judgment; it was, in his opinion, undeniable that diphtheria was now much milder than in any former year. He said it would be at least four or five years before he could give a definitive opinion about the efficacy of the new method.

Dr. Trump (Graz) gave an account of his bacteriological investigations in diphtheria cases. He found three specimens of bacilli: (1) the genuine Löffler bacillus; (2) other bacilli which were not pathological; and (3) a so-called pseudo-diphtherial bacillus which in cultures resembled the Löffler bacilli, but if inoculated in animals appeared not to be pathological. He had stated: 1. That in children affected with diphtheria the real Löffler bacillus is present also on other mucous membranes, especially on the conjunctiva and on the vulva, without producing any pathological alterations. 2. That Löffler's bacillus remained a very long time alive. He had cultivated it from a child eighty-two days after the disease was over. The virulence, however, was weakened, so that it produced only a local irritation in a guinea-pig. He had found in the mucous membranes of the eye and the nose of children who had never had diphtheria the typical Löffler bacillus. As this was principally the case in hospital patients he was of opinion that the bacillus had been introduced there by patients who came back from the diphtheria ward. 3. From these facts he concluded that persons who themselves did not offer any symptoms of diphtheria can infect other people. This infection he understood as a mere contagious one. Therefore the disinfection of the patients' homes and goods is not sufficient to avoid the propagation of the disease; the latter can only be prevented by the immunisation of the patients themselves. For this purpose the immunising qualities of antitoxins would prove to be of the greatest use.

Dr. Rauchfuss (St. Petersburg) agreed with the other speakers about the good qualities of the antitoxin, but he mentioned that myocarditis was more frequent; perhaps that might be due to the fact that a greater number of patients remained alive.

The discussion being closed the Congress, on the proposition of Professor Heubner, adopted the following motion: That this meeting is of opinion that no harm had been done to the patients by the antitoxin treatment, that the majority of observers had seen good results, and that the experiments concerning immunisation were not yet sufficient and should be continued.

CHOLERA.

THE influence of season in connexion with cholera outbreaks and epidemics in countries where that disease is prevalent, such as India, is often very striking, and it has even been said to override every other influence. Be this as it may, it is a matter of ordinary observation that the cholera of any year is not a manifestation throughout each month of the year, but there is a succession of manifestations alternately with seasons of dormancy. The cholera cause is revitalised, renewed, or reproduced, and manifests itself with certain force at certain seasons, varying to some extent with its geography. A spring cholera and a monsoon and autumn cholera are recognised, for example, in India, and

it very commonly happens in countries that have been invaded by an epidemic that a manifestation of its presence occurs about the end of March and at this season. We know that epidemic cholera has of late years prevailed in Russia; it has not yet died out there; it has only been dormant and hibernating, and the disease has of late manifested itself afresh, but mainly in a sporadic form in certain provinces and districts of that country. There have been some cases reported also in Turkey and Constantinople, and there has been a severe outbreak in the quarantine lazaretto of Camaran in the Red Sea. The first cases were reported about the end of last month. The lazaretto is at present occupied with numerous Mecca pilgrims, and a large number have recently passed through on their way to Djedda, to be soon followed by others—hence this outbreak may have much significance and importance. In another part of the East—namely, China—we learn that an outbreak of the disease among the Expeditionary Force is causing great anxiety to the Japanese Government.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF PRESIDENT.

A QUARTERLY MEETING of the Council was held on the 4th inst., Mr. Reginald Harrison, the Senior Vice-President, being in the chair.

The Council then proceeded (as reported in our last issue) to the election of a President for the remainder of the collegiate year, the vacancy being caused by the death of Mr. J. Whitaker Hulke, F.R.S. Mr. Christopher Heath was elected. Mr. Harrison then vacated, and Mr. Heath took the chair.

The Committee for General Purposes recommended that the portraits of John and William Hunter presented by the Hunter Ballie family, which had been recently received, should be reframed, and this was agreed to.

The Jacksonian Prize for an essay on the Diagnosis and Surgical Treatment of Diseases of the Liver, Gall-bladder, and Biliary Ducts was adjudged to Mr. H. J. Waring, the author of the dissertation bearing the motto "*Si torrens jecur, queris idoneum*." It was resolved that Mr. Waring should be requested to attend the next ordinary meeting of the Council on May 9th to receive the Jacksonian Prize.

Mr. Rivington, as chairman of the Jacksonian Committee, submitted two subjects for the Jacksonian Prize for the ensuing year, 1896, and the Council selected the following: "The Pathology, Diagnosis, and Treatment of Diseases of the Prostate Gland."

Two subjects were also submitted for the next Collegial Triennial Prize, and the Council selected "The arrangement and topography of the different parts of the gastro-intestinal canal in man, with special reference to the variations in their relation to the peritoneum and the occurrence of abnormalities; the subject to be illustrated from development and a comparison with the customary arrangement in other mammalian animals."

A report, dated March 18th, 1893, from the Committee of Management of the Conjoint Examining Board was read, dealing with the arrangements for the third and fourth examinations under the new regulations, and the suggested examination in ophthalmic medicine and surgery. These matters were then referred to a special committee, composed of the President and Vice-Presidents, Mr. Hutchinson, Mr. Bryant, Sir William MacCormac, Mr. T. Pickering Pick, Mr. Howse, Mr. Howard Marsh, and Mr. Morris. The report also dealt with the recognition of several institutions as places of instruction in chemistry, physics, practical chemistry, and biology, the recognition of a course of laboratory instruction in public health at the Westminster Hospital Medical School, and the recognition of the City of London Hospital for Diseases of the Chest as a place of study during the fifth year of the curriculum. These portions of the report were approved and adopted.

A report, dated March 8th, 1895, from the Laboratories Committee was read, approved, and adopted. It was as follows:—

1. *The work in diphtheria for the Metropolitan Asylums Board.*—(a) Examination of material for diagnosis. Since Jan. 1st 1145 specimens have been examined and reported

upon. In some cases the report is issued on the same day that the specimen arrives; but in the majority of cases the examination necessitates as much as twenty-four hours' work. An accurate record has been kept of the examination of each case, including the various organisms found. During the first seven weeks the director with two assistants examined all the cases, but since the third week in February Mr. Card has relieved the director of the superintendence of the microscopic examination of some of the specimens. The work goes on very smoothly, and is now being accomplished more rapidly than at first. The director has undertaken to report fully to the Metropolitan Asylums Board on every 500 cases examined. (b) The preparation of antitoxin serum. After some unavoidable delay the Metropolitan Asylums Board placed at the director's disposal stabling for fifteen horses at Tooting; four horses are being prepared, all of them are in good health, and in three cases the treatment is well advanced. As soon as these horses are ready the supply of serum will be ample, and it is intended that one or two reserve horses shall be prepared. It is probable that the serum will be ready for use at an early date.

2. *The Goldsmiths' Company's grant for researches on the antitoxin treatment of diphtheria, &c.*—The Committee, seeing their way to placing a certain quantity of antitoxic serum at the disposal of investigators, have for the purposes of experiment determined to make a grant of £100 to Dr. Sidney Martin for the purpose of working out the action of the antitoxic serum when used to counteract the effects of various poisons separated by him from the membrane and from the spleen in cases of diphtheria. This appears to the Committee to be a most important question, and one that must be settled before the mode of action of antitoxic serum can be understood, and they feel that no one can better undertake this work than Dr. Martin. The Committee have some other lines of research under consideration, on which they will fully report to the Colleges in due course.

A letter was read—signed by the President, Vice President, and Secretary of the Royal College of Surgeons in Ireland—expressing the regret of that College at the death of the President of the Royal College of Surgeons of England. It was moved and carried unanimously that the thanks of the Council be conveyed to the Royal College of Surgeons in Ireland for the kind words of sympathy contained in their letter.

A letter was read from the Registrar of the General Medical Council stating that Mr. Charles Tomes has been appointed by that Council as Visitor of the Dental Examinations of the College, and that he will visit and inspect these examinations during the present year.

Mr. Hutchinson moved: "That steps be taken to obtain busts of the late Sir William Savory, Bart., F.R.S., and the late Mr. J. W. Hulke, F.R.S." The matter was referred to a committee consisting of the President, Vice-Presidents, and Past Presidents to consider and report.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6611 births and 4280 deaths were registered during the week ending April 6th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 35.0 to 23.4 per 1000, further fell last week to 21.1. In London the rate was equal to 19.0 per 1000, while it averaged 22.6 in the thirty-two provincial towns. The lowest rates in these towns were 10.9 in Croydon, 13.1 in Huddersfield, 15.2 in Plymouth, 15.4 in Nottingham, and 15.7 in West Ham; the highest rates were 26.9 in Birmingham, 27.0 in Blackburn, 28.5 in Oldham, 31.9 in Preston, and 33.0 in Burnley. The 4280 deaths included 274 which were referred to the principal zymotic diseases, against 314 in each of the two preceding weeks; of these, 93 resulted from whooping-cough, 53 from measles, 51 from diphtheria, 38 from diarrhoea, 21 from scarlet fever, 17 from "fever" (principally enteric), and one from small-pox. No fatal case of any of these diseases occurred last week either in Bristol, Bradford, or Birkenhead; in the other towns they caused the lowest death-rates in Newcastle-upon-Tyne, Gateshead, and Huddersfield; and the highest rates in Manchester, Cardiff, Salford, and Burnley. The greatest mortality from measles occurred in Cardiff, Sheffield, and Bolton; and from whooping-cough

in Norwich, Salford, Preston, Burnley, and Portsmouth. The mortality from scarlet fever and from "fever" showed no marked excess in any of the thirty-three large towns. The 51 deaths from diphtheria included 23 in London, 5 in Birmingham, 4 in Manchester, and 3 in West Ham. One fatal case of small-pox was registered in Derby, but not one in London or any other of the large towns. There were 53 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, April 6th, against 57, 58, and 55 at the end of the three preceding weeks; 7 new cases were admitted during the week, against 12, 14, and 10 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1519, against 1615, 1587, and 1555 on the three preceding Saturdays; 143 new cases were admitted during the week, against 184 and 161 in the two preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 1448 to 497 in the five preceding weeks, further fell to 427 last week, but were 17 above the corrected average. The causes of 69, or 1.6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Salford, Leeds, Newcastle-upon-Tyne, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the five preceding weeks from 42.8 to 25.4 per 1000, further fell to 24.7 during the week ending April 6th, but exceeded by 3.6 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18.9 in Perth and 20.0 in Edinburgh, to 26.6 in Dundee and 30.3 in Aberdeen. The 713 deaths in these towns included 25 which were referred to whooping-cough, 22 to measles, 17 to diarrhoea, 3 to small-pox, 3 to "fever," 2 to diphtheria, and 2 to scarlet fever. In all, 74 deaths resulted from these principal zymotic diseases, against 115 and 90 in the two preceding weeks. These 74 deaths were equal to an annual rate of 2.6 per 1000, which was 1.3 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 27 and 26 in the two preceding weeks, were 25 last week, of which 13 occurred in Glasgow, 5 in Dundee, and 4 in Leith. The deaths referred to measles, which had been 48, 56, and 35 in the three preceding weeks, further declined to 22 last week, and included 7 in Edinburgh and 7 in Aberdeen. The 17 fatal cases of diarrhoea exceeded by 3 the number in the preceding week, and included 9 in Glasgow. The 3 deaths referred to different forms of "fever" corresponded with the number in the preceding week, and included 2 in Dundee. The fatal cases of diphtheria, which had been 9 and 5 in the two preceding weeks, further declined to 2 last week. Of the 3 deaths from small-pox, 2 were recorded in Glasgow and 1 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 313 and 199 in the two preceding weeks, further declined to 189 last week, but were 74 above the number in the corresponding week of last year. The causes of 62, or nearly 6 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 42.4 to 48.6 per 1000 in the three preceding weeks, declined again to 43.3 during the week ending April 6th. During the thirteen weeks of last quarter the death-rate in the city averaged 37.1 per 1000, the rate during the same period being 26.0 in London and 30.5 in Edinburgh. The 290 deaths registered in Dublin during the week under notice showed a decline of 36 from the number in the previous week, and included 11 which were referred to the principal zymotic diseases, against 7 and 12 in the two preceding weeks; of these, 4 resulted from whooping-cough, 3 from small-pox, 3 from diarrhoea, 1 from "fever," and not one either from measles, scarlet fever, or diphtheria. These 11 deaths were equal to an annual rate of 1.6 per 1000, the zymotic death-rate during

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON—MARCH, 1895.
(Specially compiled for THE LANCET.)

* Including 31 cases of membranous group.

† Including deaths from membranous group.

the same period being 1·4 in London and 2·3 in Edinburgh. The 4 fatal cases of whooping-cough exceeded the number recorded in recent weeks. The deaths referred to small-pox, which had been 4, 5, and 1 in the three preceding weeks, rose again to 3 last week. The three fatal cases of diarrhoea corresponded with the number in the previous week, while the mortality from "fever" showed a marked decline. The 290 deaths registered in Dublin last week included 44 of infants under one year of age and 111 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons almost corresponded with the numbers in the previous week. Three inquest cases and 3 deaths from violence were registered; and 96, or nearly a third, of the deaths occurred in public institutions. The causes of 17, or nearly 6 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MARCH, 1895.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during March in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 5·8 per 1000 of the population, estimated at 4,392,346 persons in the middle of this year. In the three preceding months the rates had been 8·4, 7·0, and 5·9 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Paddington, St. Giles, City of London, St. Saviour Southwark, St. Olave Southwark, and Woolwich; while they showed the largest excess in Fulham, Strand, Limehouse, Poplar, Rotherhithe, Camberwell, and Greenwich. The prevalence of small-pox in London showed a slight decline during March, 41 cases being notified during the month, including 10 in Rotherhithe, 9 in Marylebone, 7 in Greenwich, and 4 in Holborn sanitary areas. The Metropolitan Asylum Hospitals contained 54 small-pox patients at the end of March, against 16, 51, and 66 at the end of the three preceding months; the weekly admissions averaged 11, against 3, 10, and 15 in the three preceding months. The prevalence of scarlet fever in London during March showed a slight decline from that recorded in the preceding month; this disease was proportionally most prevalent in Fulham, Strand, Limehouse, Poplar, Rotherhithe, Wandsworth, Camberwell, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 1485 scarlet fever patients at the end of March, against 1865, 1633, and 1569 at the end of the three preceding months; the weekly admissions averaged 145, against 171, 148 and 141 in the three preceding months. The prevalence of diphtheria in London showed a slight increase during March; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Limehouse, Mile End Old Town, Poplar, Rotherhithe, Battersea, Camberwell, and Greenwich. There were 435 cases of diphtheria under treatment in the Metropolitan Asylum hospitals at the end of March, against 521, 515, and 461 at the end of the three preceding months; the weekly admissions averaged 62, against 93, 71, and 50 in the three preceding months. The prevalence of enteric fever in London showed a slight decline during the month under notice; among the various sanitary areas this disease showed the highest proportional prevalence in Poplar and Camberwell. Erysipelas was proportionally most prevalent in St. Pancras, Holborn, and Rotherhithe sanitary areas. The 13 cases of puerperal fever notified during March included 3 in Islington, 3 in Lambeth, and 2 in Battersea sanitary areas.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, March 30th, the deaths of 10107 persons belonging to London were registered, equal to an annual rate of 30·0 per 1000, against 17·7, 18·3, and 30·3 in the three preceding months. This high rate was principally due to the epidemic prevalence of influenza. The lowest death-rates during March in the various sanitary areas were 20·8 in Hampstead, 22·9 in Stoke Newington, 23·3 in Plumstead, 23·5 in Lee, 23·8 in Woolwich, and 25·2 in Wandsworth; the highest rates were 35·0 in Westminster and St. Giles, 35·1 in Shoreditch,

38·6 in Newington, 39·3 in Holborn, 40·3 in St. George Southwark, and 40·5 in Strand. During the four weeks of March 508 deaths were referred to the principal zymotic diseases in London; of these, 203 resulted from whooping-cough, 114 from diphtheria, 77 from measles, 55 from diarrhoea, 38 from scarlet fever, 20 from different forms of "fever," (including 1 from typhus fever, 18 from enteric fever, and 1 from an ill-defined form of fever), and 1 from small-pox. These 508 deaths were equal to an annual rate of 1·5 per 1000, against 1·6 and 1·5 in the two preceding months. No fatal case of any of these diseases was recorded last month in Stoke Newington or in Woolwich; in the other sanitary areas they caused the lowest death-rates in Paddington, Hampstead, City of London, St. Saviour, Southwark, Wandsworth, and Plumstead; and the highest rates in St. Martin-in-the-Fields, Limehouse, St. Olave Southwark, Rotherhithe, and Greenwich. Only 1 fatal case of small-pox was registered in London during the month under notice, the corrected average in the corresponding periods of the ten preceding years being 13; this fatal case belonged to Marylebone sanitary area. The 77 deaths referred to measles were little more than a third of the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Hackney, Holborn, Shoreditch, Limehouse, Poplar, and Battersea. The 38 fatal cases of scarlet fever were 23 below the corrected average number; the mortality from this disease showed no marked excess last month in any of the sanitary areas. The 114 deaths from diphtheria almost corresponded with the corrected average number; this disease showed the highest proportional fatality in Westminster, St. Martin-in-the-Fields, Mile End Old Town, Camberwell, and Greenwich sanitary areas. The 203 fatal cases of whooping-cough were 84 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. James Westminster, St. Luke, Shoreditch, Limehouse, Newington, Lambeth, and Lewisham. The 18 deaths referred to enteric fever were little more than half the corrected average number; there was no marked excess of "fever" mortality last month in any of the sanitary areas. The 55 deaths from diarrhoea were within one of the corrected average number. In conclusion, it may be stated that the mortality in London during the month under notice from these principal zymotic diseases was as much as 36 per cent. below the average.

Infant mortality in London during March, measured by the proportion of deaths under one year of age to registered births, was equal to 193 per 1000, and considerably exceeded the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. Giles, St. Luke, City of London, Whitechapel, Mile End Old Town, and Wandsworth; and the highest rates in Fulham, Westminster, St. James Westminster, St. Martin-in-the-Fields, Strand, and Newington.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR FIB JAMES R. A. CLARK, Bart., F.R.C.S. Edin., retires from the service, receiving a gratuity. Surgeon-Captain Vere E. Hunter to be Surgeon-Major. Surgeon-Captain Frederick T. Skerrett, F.R.C.S.I., from half-pay, to be Surgeon-Captain, vice A. Wright, seconded.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments are announced:—10th Bombay Infantry: Surgeon-Major Adey to the Medical Charge, vice Surgeon-Captain Arnim, transferred permanently to the Civil Department, and Surgeon-Lieutenant B. H. F. Leumann, M.B., Officiating Medical Officer, to act as Civil Surgeon. 29th Bombay Infantry: Surgeon-Captain Heath to the Medical Charge, vice Surgeon-Major Adey, transferred. Surgeon-Captain T. W. Shaw, M.B., (Bombay), is confirmed in the appointment of Medical Officer 1st Regiment Central India Horse, and of the Gocna Political Agency. Surgeon-Majors H. McCalman and D. C. Davidson have respectively delivered over and received charge of the Dharwar Prison, and Surgeon-Captain S. E. Pratt, M.B., B.S., and Brigade-Surgeon-Lieutenant-Colonel C. T. Peters, M.B., have delivered over and received charge of the Bijapur Prison. Surgeon-Major A. Milne (Bombay Establishment), Deputy Assay Master, Calcutta, is transferred to Bombay as

Deputy Assay Master. Surgeon-Captain Whitcombe, on return from leave of Surgeon-Major Maitland, has been transferred to general duty, Poona.

NAVAL MEDICAL SERVICE.

Staff-Surgeon H. X. Browne is appointed to the *President*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major Arthur O. Wiley, having resigned his Volunteer appointment, ceases to be an officer of the Army Medical Reserve of Officers. Surgeon-Captain William Chalmers-Cowan to be Surgeon-Major.

MILITIA MEDICAL STAFF.

Surgeon-Lieutenant-Colonel C. Whipple, 3rd Battalion the Devonshire Regiment, resigns his commission; also is permitted to retain his rank and to wear the prescribed uniform on his retirement.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Duke of Cornwall's Light Infantry: Surgeon-Lieutenant J. W. Haughton is appointed Second Lieutenant. Surgeon-Captain (Honorary Surgeon-Major) R. C. M. Pooley resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement. 2nd Volunteer Battalion the King's (Shropshire) Light Infantry: Surgeon-Captain C. H. Gwynn, M.D., to be Surgeon-Major. 1st (Ross Highland) Volunteer Battalion Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Surgeon-Lieutenant C. Mackenzie, M.B., resigns his commission.

OVERCROWDING AND DEFECTIVE VENTILATION IN RELATION TO PNEUMONIA.

The writer of the article on the "Sanitary State of the German Army" in the March number of *The Medical Magazine*, advertising to the prevalence of pneumonia in the armies of Germany and France and the alleged infectious nature of the disease, alludes to his own experience of this so-called infectious pneumonia during the war in South Afghanistan. Attendants on the sick were freely attacked, and the general opinion then was that the malady was most infectious. The men were greatly overcrowded and every aperture was closed to keep out the cold, which was extreme, so that the atmosphere in which they lived was very foul. The disease rapidly spread, and under these conditions no doubt manifested infectious properties; but the writer adds that, given pure air and free ventilation, he is convinced there is no danger of the disease spreading by reason of propinquity alone from the sick to the healthy. There is no doubt that overcrowding and foul air are very powerful predisponents, at any rate, to attacks of pneumonia in winter and early spring, especially among those who have previously suffered from malarious disease. The lungs in such subjects become congested, inflamed, and hepatized with almost the ease and rapidity with which the spleen swells in attacks of ague. This has been the experience of medical officers serving with troops in India and in campaigns in that country; the disease may spread in foul and unventilated tents and buildings with the apparent rapidity of typhus. A great many years ago there was an outbreak of pneumonia in the ironclads of the Mediterranean fleet, almost resembling an epidemic, attributable, no doubt, to a similar cause—bad ventilation. An infection can apparently be manufactured under certain conditions.

SURGEON-GENERAL SAVILLE MARRIOTT PELLY,
C.B., F.R.C.S. ENG.

Surgeon-General S. M. Pelly, who died suddenly on the 3rd inst. at his residence, Lee, aged seventy-six, retired in 1870 with the rank of Inspector-General. He was attached to the Bombay Army and served with the Sind Irregular Horse during the campaign of 1844-45 against the border tribes of Cutch. He was present at the capture of Shahpoor, for which he was mentioned in the despatches. He also served under Sir C. Napier, 1846-47, and was with the Sind Horse under Major John Jacob. During the Mutiny campaign in 1857-58 he served with the 2nd Regiment Light Cavalry in Rajpootana. Under Napier in 1867-68 he acted as principal medical officer of the Indian Medical Department throughout the Abyssinian campaign, for which he received the Companionship of the Bath. For his services during the Mutiny campaign he received the Indian medal and clasp for Central India. We have in type an extended obituary notice of this distinguished officer, but owing to pressure on our space we are unable to print it this week.

INDIAN ARMY REORGANISATION.

The reorganisation of the Indian Army under the Act of Parliament of 1893 has been effected. The military control hitherto exercised by the Governors in Council of Madras and Bombay is at an end, and the Indian Army is now a unified army. The Commander-in-chief in India, Sir George White, has supreme command. The Bengal Army is divided into two, that for the Panjab and Bengal, and with the armies of Madras and Bombay will form the four great commands under their respective generals and staff. The principal medical officer of the Panjab command is Surgeon-Colonel Harvey, I.M.S., and of the Bengal command Surgeon-Major-General Walsh, Army Medical Staff.

The epidemic of measles unfortunately continues to spread among the boys on board the training ship *Impregnable* at Devonport. More than fifty cases have been removed to the Royal Naval Hospital, and all newly-arrived boys are received in the gunboat *Circus*.

The transport *Warwick Castle* is daily expected to arrive at Portsmouth with nine patients for Netley from Bermuda.

Correspondence.

"Audi alteram partem."

"THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED."

To the Editors of THE LANCET.

SIRS,—I have read the letters about the London and Manchester Assurance Company. I have fifty-seven patients on my list for this company, and receive £2 17s. on quarter day, which in a small practice is not to be despised. None of the patients I have been called to attend have been in a position to pay a bill, and if I object to any member as being of too good a social (or rather financial) position, I believe if I write to the secretary the agent is told to take them off my list. The money I receive from the London and Manchester Assurance Company, though small, is better than any other club I have had to do with—e.g., Hearts of Oak, Oddfellows, Rechabites, &c., because the money is paid regularly and the secretary is never "hard up" and asking the medical man to wait a month or two (once I had to wait fifteen months for the local secretary of a club to pay up). The average pay is also better than our provident dispensary, which has a maximum of 4d. a week for any family. A family of eight pays me 4d. In the case of the London and Manchester Assurance Company I get 8d. a week for the same, and the reduction from 1s. a quarter to 10d. only takes place when I have 100 members on my list. All the medical men I have consulted who are on it seem pleased with it, and there are now 1200 qualified men engaged with the company. Should any of us resign we are bound to give three months' notice by next quarter day. I must be guided by the conduct of others as to resigning. If I feel it my duty I shall do so, though I am no doubt popular from the fact that my list nearly doubles every quarter, and in about eighteen months I shall probably draw nearly £100 a year from the company, and I can ill afford to lose the money. It is only fair to the company to say that though they pay us less than they collect, yet in many cases the people on our list cease payment at once, yet the company pay us all the same. The subject is a large one, and I have not been concise, but I should be glad to hear the views of the profession further through your columns, if possible.

I am, Sirs, yours very truly,

C. C.

April 4th, 1895.

To the Editors of THE LANCET.

SIRS,—I feel sure the above subject, chosen by "A General Practitioner," is a strong one and ought to be taken up by the medical profession generally, so that it can be thoroughly ventilated and amply digested by all young practitioners. At the same time, I think if the term "Medical Aid Companies" were used instead of mentioning one, perhaps a more general conclusion will finally be arrived at. Mr. Woodward's letter is extremely amusing, especially when one glances at the figures given at the end of this letter. I question very much if the managing director has ever had the opportunity of inspecting such statistics before, although he rushes into

print to laud his company's doings, and to try to cover the system of "touting" which certainly exists in a determined way, but at the same time ridiculed by both directors and local managers alike. As my intention in this correspondence is only to give a few figures, I must not go further into this matter, but will on another occasion, if wished, go into greater detail. Being compelled through ill-health to leave town, I took a couple of years' rest, and as an opportunity cropped up for me to enter into, and carefully watch, the medical aid system, I decided to throw my whole time and energy in it. A certain sum—£100—was guaranteed to me; but before I commenced I positively refused to allow anything unprofessional to be done. Having settled thus far my duties commenced, after taking the wise precaution to obtain a surgery about a mile and a half from my house, so that I could keep a very accurate account of all proceedings. Now, if our friends will kindly look through the few following figures (which I can give in more detail if needed), they will see that when Mr. Woodward, in his letter of March 30th, talks of pecuniary assistance to the medical profession he speaks of something which he has certainly not inquired into, or otherwise his mathematics must have been grossly neglected; for the simplest rules only are needed to produce a result exactly opposite to those suggested in his letter.

The figures are given for one year, from March 25th, 1894, to March 25th, 1895, when I resigned:—

	No.	No.
Bottles to June quarter	480	—
Visits " " " " " " " " " "	—	131
Bottles to September quarter	568	—
Visits " " " " " " " " " "	—	168
Bottles to December quarter	873	—
Visits " " " " " " " " " "	—	441
Bottles to March quarter	579	—
Visits " " " " " " " " " "	—	248
Total bottles for year	2500	—
Total visits for year	—	988

	£	s.	d.
Cheque to June quarter	6	5	2 on 400 cards.
" " September quarter	10	19	9 " 374 "
" " December quarter	15	10	7 " 696 "
" " March quarter (but approximate)	16	0	0 " 700 "

Total cheque for year 48 15 6

Now if this grand sum be divided by the number of bottles and visits I think a large fee of 3½d. will be the result. I now leave the pecuniary advantages—of Mr. Woodward—to the medical profession, young and old; at the same time I have a host of other information which I am prepared to communicate. I am, Sirs, yours faithfully,

April 3rd, 1895.

ALEXANDER M. MOORE.

To the Editors of THE LANCET.

SIRS,—One would imagine from Mr. Woodward's letter in your issue of March 30th that in supplying medical relief to policyholders his society's only motive is to inculcate self-help in those who object to receiving charity. I think I can supply another motive. I am a medical referee to an assurance society which does a very large business among the poorer class. The local agent of this society called upon me and asked if I would allow him to "run" a medical club in conjunction with his ordinary business, for unless he could "promise them the doctor in time of illness" he could not get people to insure their lives through him, and he was utterly unable to compete against the agents of the "London and Manchester," who held out the medical club as an inducement to people to insure through them. This agent assured me that wherever he went in search of "lives" the first question was, "Can we have the doctor as well?" The medical man is thus a sop with which to procure other business. The "touts" of this society are all-powerful, and do not appear to be under any proper control from headquarters.

I am, Sirs, yours faithfully,

BETA.

April 8th, 1895.

To the Editors of THE LANCET.

SIRS,—I am pleased to see the correspondence about this company. Were the members allowed entrance confined to

the lower working class, and the healthy of such, there might be something in its favour even at the fee paid by the company for each. But I deny that it is confined to the lower working class. I know scores of exceptions, as I can instance. I know a man who entered who paid a medical man not much short of £30 for considerably less than twelve months attendance upon a member of his family, and he was well able to pay it as he was a considerable property owner; a schoolmistress, single, with salary about £80 a year; publicans in good trade; employers of labour; people who can employ domestic servants; people with shops doing good business; people with pianos, and who can afford music lessons for their children; clerks and well-to-do artisans, earning 30s. a week and over; people who come to the medical man's surgery, gloved and well-dressed, frequently without the usual bottle, often ignoring surgery hours, and expecting to be attended to or visited at any hour. Then the delicate one or ones of the family are frequently those entered. There is no medical examination. I know the company can reply that the medical man has power to reject whom he thinks unhealthy if they come early under observation, but if the rejected happen to have been private patients of his, in most instances he or she feels sore and leaves him, and the agent thinks he has a grievance because, I suppose, he loses the entrance fee. I know of people with uterine disease, hernias, ulcers, old age &c. entered. There is a proposal form with questions as to health to be filled up by the proposer. May I ask the managing director how often the proposer fills this up himself or herself? or if the agent fills it up, how often he puts the questions down on it to proposer or parents if it happens to be a child? How often the questions are seen at all by the proposer? To do the London and Manchester justice, I believe there are other companies which pay medical referees even less, but even this is a grievance, as sometimes those in the London and Manchester think they are in something "genteel" and say they are not ordinary "club patients." I can vouch for foregoing statements.

I am, Sirs, yours faithfully,

April 8th, 1895.

INTERESTED.

"THE WOMEN'S FREE HOSPITAL, SOUTHAMPTON."

To the Editors of THE LANCET.

SIRS,—In reply to a statement appearing in your issue of March 30th, we beg you will insert the following answer. The committee of the Women's Hospital are strongly of opinion that it would have been a more dignified course for the Medical Society to have taken if they had requested the Editors of THE LANCET to publish the whole correspondence, and not an entirely inaccurate, prejudiced, and misleading statement such as they have done, deliberately suppressing all the opinions of the Hospital Committee. To the public the verdict of the Southampton Medical Society may sound as a voice of great importance, but this attack has been conducted principally by the committee of the society, consisting of nine gentlemen, and the committee of the Women's Hospital have every reason to believe three of these gentlemen have taken no active part in the deliberations, and that of the other six, three are on the staff of another institution, including the chairman, and at least one of the answers to a request from the Hospital Committee was sent to this committee without the answer being brought before the whole society, and the resolutions were passed by a body of twenty-seven gentlemen out of a society of fifty members. It may be of interest in weighing the importance of the deliberations of the Southampton Medical Society for it to be known that at least three prominent members of the profession (one a gentleman who has been present at a large number of the operations performed, one who from actual experience knows how the work is carried on) have resigned their membership of the Southampton Medical Society, as they entirely disapprove of and disagree with the action some members of the society have taken. After a few explanatory remarks, the committee wish to tabulate the allegations, insinuations, or charges (it is rather difficult quite to know which is the correct word), which with much difficulty they have abstracted from the rambling compositions of Mr. Bullar and the printed statement of the Medical Society; then to answer these statements one by one; and finally to bring a few prominent facts clearly before the medical profession. To save repetition we enclose you the whole of the correspondence, and we will only refer to each letter, which references you will doubtless verify.

It has been reported to several members of the committee that patients who have attended the hospital have been

sought out and catechised as to the opinion &c. that were given them, and that in some cases "evidence" has been committed to writing. Such reports naturally shake the confidence of the committee as to the unprejudiced nature of the attack that has been made, although the committee were loth to believe that any member of the Southampton Medical Society could have adopted such a reprehensible method, seeing how well it is known that great care must always be exercised in accepting any statements made by patients—especially women—about one medical man or hospital to another practitioner or institution. The committee hoped these reports would have been contradicted by the Medical Society answering these questions as to "when" and "by whom" the evidence was obtained that warranted the society in making the accusation it has done. A large bulk of the statements of the Medical Society can easily be disposed of, as the committee have already expressed their view on friendly criticism as opposed to hostile attacks (Letter 2, p. 6), and on questions of management as well as on questions of finance (see Letter 2, p. 7), which they are of opinion are matters concerning the subscribers, and not Mr. Bullar. As far as the committee are able to discover, the charges which Mr. Bullar has tried to make are—(1) against the constitution, work, and management of the hospital; (2) that the hospital is not free; (3) that the medical officer reported on the nursing staff; (4) that the secretary has not access to the books; (5) that the question of finance is not sufficiently explicit in the reports; (6) that operations are recklessly and unjustifiably performed, and results are not sufficiently reported; (7) that the staff is deficient; (8) that the committee have not proper control; (9) there are no rules; (10) that five operations have been done without proper consultation; (11) that the committee refused a committee of inquiry; (12) that Dr. Playfair supported the view; (13) that Dr. Playfair has resigned; (14) that Mr. Elliot has no special knowledge of the diseases peculiar to women; (15) that operations have been advised, not performed, and the patients are now alive and well.

1. As regards "constitution," the committee have answered (Letter 2, p. 6). As regards "work" this will be referred to again. As regards "management," again we refer to Letter 2, p. 5. The committee clearly stated that they thought it incredible that a professional man should endeavour to prejudice an existing institution by bringing forward questions of this kind, which can have no bearing whatever upon the present work of the hospital or its utility as a public institution. The committee have pointed out in their report that the hospital has laboured under many disadvantages during the past—the death of a lady who took an active part in starting the hospital, and the loss of the chairman of the committee, the Right Rev. Bishop Perrin, who left Southampton when he was created Bishop of Columbia. All this was known to the Medical Society, who seized on this opportunity to attack the institution. 2. The statements made by the Medical Society are not true. No hospital patient has to pay £2 2s. a week, and the arrangements made for defraying the expense of in-patients is a matter which concerns the subscribers, and not Mr. Bullar or the Southampton Medical Society. The actual arrangements are as follows:—Originally the out- and in-patients were treated in the same building—which arrangement ceased upon the advice of the medical staff, as they found it was inadvisable to perform serious operations in a building to which out-patients came, and in consequence arranged (as a temporary measure, until they could build permanent premises) with their medical officer to receive their two beds in a ward in his private hospital for the exclusive use of hospital patients. The same kind of arrangement was employed by the founders of the Hospital for Women at Birmingham many years ago, where it was found that the presence of out-patients in a building where serious operations are performed is seriously prejudicial to the latter. In the majority of cases patients have been treated without payment of any kind, but on account of the low state of the funds of the hospital some patients have been asked if they could afford to pay a small sum towards the out-of-pocket expenses, and this they have gladly done, from sums varying from 5s. a week up to, but never exceeding, £2 2s. a week, only four ever having paid this latter amount. No patient has ever been refused treatment on account of inability to contribute towards her expenses, and as it has been insinuated by the Medical Society that their medical officer might have derived some pecuniary benefit by

this arrangement the committee are glad of this opportunity of giving a most emphatic denial to this most unworthy conclusion. 3. Refer to Letter 2, p. 7. This was fully answered and the committee considered Mr. Bullar's remark as impertinent. The medical officer will continue to report from time to time, to the committee, on such matters of so great importance as that of nursing. One great reason for giving this report was that through the kindness of Mr. Lawson Tait one of his most experienced nurses resided here for some months, in order to teach some of the nursing staff who nursed hospital in-patients Mr. Tait's special details in nursing abdominal section. Reports regarding nursing are regularly included in the Medical Board's annual report at the Birmingham Women's Hospital. 4. This at first sight appears an error of management. The reply of the secretary of the Southampton Women's Hospital intended politely to convey to Mr. Bullar the fact that the books were inaccessible to the hon. secretary for the purpose of giving information and statistics to any person who chose to ask for these for the purpose of formulating attempts to damage the institution. 5. This the committee have referred to, and decline to receive interference on the point from the Southampton Medical Society, as being one purely of finance and affecting themselves and their subscribers alone. The accounts we published in the printed reports of the hospital, which are in your possession. 6. This the committee consider the pith of the whole attack, and, in order to raise a definite issue, the committee will confine themselves to dealing with the 24 cases referred to by Mr. Bullar.

Nineteen out of the 24 cases were seen by Mr. Lawson Tait, and operation proved in each case the diagnosis was correct. This leaves a balance of five cases. These latter operations were as follows: (1) pyo-salpinx (successful, with recovery); (2) suppurating hæmatocele (intra-peritoneal, urgent); (3) cystic ovaritis (intra-peritoneal, urgent); (4) chronic salpingitis and ovaritis (intra-peritoneal, urgent); (5) pyo-salpinx (intra-peritoneal, urgent). Ample assistance was always procured; as a matter of fact, a member of the Southampton Medical Society itself was present in four of the five cases and thoroughly approved of everything that was done, and the committee have been personally assured of this by the member himself, and the specimens in Mr. Elliot's possession amply prove the wisdom and propriety of operating in these cases. It may be well here to state that, although this charge was never absolutely definitely framed, it was hinted at both in print and by various members of the society to their various patients, and has been used as a weapon and (what the Medical Society has considered) a powerful argument against the hospital. Knowing this, Mr. Lawson Tait and Mr. Elliot thought it would be the fairest way to read a paper on all the cases which had been operated on, and Mr. Lawson Tait wrote and made this offer to the Southampton Medical Society, but apparently the society was loth to hear the truth, and preferred to continue to cast innuendoes "about what they knew," as they treated the offer with absolute and most discourteous silence, never even acknowledging to the committee the receipt of Mr. Tait's letter. The committee do not think they need refer any further to this matter. All this was clearly stated in the correspondence, but suppressed by the Southampton Medical Society. It may be also well to add that all professional information asked for by the Southampton Medical Society was immediately given. (See tables at end of Letter 2.) The statistics were copied from the books, and the only cause of complaint could but be that they had not been properly published. In the report that was next published the committee gave additional information on the subject of the operations—more information than is to be gleaned from the published reports of any other institution in the town—and in the face of this the Medical Society have seen fit to use this complaint as a weapon against the hospital in their statement published in THE LANCET. The committee, in Letter 2, pp. 6 and 7, express their views about ratios as to number of operations, and to avoid repetition they beg to refer you to such letter. The committee cannot deal with ratios, but with facts and individual cases. The committee venture to think that you will agree with them that it is not fair to compare a hospital like the Chelsea Hospital for Women, dealing with an enormous number of cases, to a small hospital in a provincial town carried on for a special purpose, to which naturally only a comparatively small number would go. 7. It may be so in the opinion of the Southampton Medical Society, but it is the

opinion of the committee that it is "sufficient" and "efficient." We refer in connexion with this statement to Mr. Lawson Tait's letter, bearing date Oct. 22nd, 1894, published in THE LANCET, explaining the reason for the constitution of the staff of which the Medical Society complained. 8. The committee beg to state they have absolute control. 9. The rules which have been made from time to time have been drawn up, and are printed in the last report. Notwithstanding their knowledge of this, the Southampton Medical Society make complaint of it in THE LANCET. 10. This is so. As referring to the 24 operations, it is stated that Mr. Lawson Tait saw 19 of the cases. Of the other 5 cases above referred to, 2 were cases of emergency (Cases 2 and 5); 1 Mr. Lawson Tait was prevented from being present at (Case 4) owing to illness, and the other 2 were cases demanding operation. In each of these cases, as before stated, the most efficient and able assistance was procured, and the committee are satisfied that every care and precaution has been taken, and there is absolutely no cause for complaint. 11. This seems a serious offence in the eyes of the Medical Society, but the committee of the Women's Hospital have been unable to come to the conclusion that the attack made upon them by the Medical Society is of a genuine and public-spirited character, and they therefore took the view—and still strongly maintain it—that they would not listen to the proposal for a committee of inquiry until they, as the responsible body, had been informed *clearly and definitely*, not as mere vague insinuation, what the charges were which they were called upon to answer. The committee think that had they been acquainted with detailed charges and failed to investigate them *satisfactorily*, then the Southampton Medical Society might have thought they had a ground on which to base their suggestion. The committee offered to investigate any such charges and to *fully acquaint the Medical Society with the action they had taken in the matter*. The committee did refuse the proposal, and see no reason to alter their opinion; but it must not be thought from this that the committee of the Women's Hospital ever had any desire to avoid publicity. The Southampton Medical Society held out as an inducement to the committee to accede to their request "that further publicity would thus be avoided." To this somewhat extraordinary proposal the committee replied: "And we refuse to join with the Medical Society in any arrangements which would have the effect of concealing anything which, in the public interest or in the interest of medical science, should be known." We trust, however, from the full information that we have afforded, you will readily see that the committee have nothing whatever to conceal, and you are quite at liberty to publish the whole of the correspondence that has passed, and they would be only too ready to consider and accept *bona-fide* suggestions for the improvement of their institution. 12. The committee exceedingly regret having publicly to express their views on this point, but it is necessary to do so. They are of opinion that Dr. Playfair has treated them in a most discourteous manner. He listened to the accusations of the Medical Society. He never communicated with the committee or the staff of the hospital to which his name was attached, and the committee of the Women's Hospital received a letter from the *Secretary of the Medical Society*, to whom Dr. Playfair had written, saying he strongly approved of the proposal of the Medical Society as to holding a committee of inquiry. Dr. Playfair, *without being fully informed of the facts*, expressed his opinion, agreeing with the Medical Society, and therefore the committee of the Women's Hospital did not see the necessity of taking Dr. Playfair's advice into consideration. The committee are of opinion that Dr. Playfair should have resigned before throwing in his lot with the party adverse to the interest of the hospital, or declined to have given an opinion until he had received the view of the Hospital Committee. 13. Dr. Playfair has resigned under the circumstances stated above, and under the circumstances the committee see no reason to regret the course he has taken. 14. The committee very much regret that they are called upon to defend the reputation of one of their medical officers. The committee prefer to take the opinion of those gentlemen who know Mr. Eliot and know from actual experience and observation what his capabilities in this particular branch of practice are. And, apart from these opinions, the fact that Mr. Eliot has for some years past worked with Mr. Lawson Tait (witnessing Mr. Tait's operations, and operating himself under Mr. Tait's immediate observation) is quite sufficient to warrant the committee of the hospital in again endorsing the statement referred to in THE LANCET by the

Medical Society, and they are quite conscious of the fact that the success that has attended the work under their control is in a large measure due to the fact that Mr. Eliot has been and is always availing himself of every opportunity to acquire a knowledge of the most modern methods of treatment in this particular branch of practice, and the view the committee hold is fully borne out by the statement contained in Mr. Tait's letter. 15. It is almost incredible that a body of gentlemen could publish such a statement. In no one single instance have the Medical Society asked for information, but seem quite ready to rely on the bare statement of a hospital outpatient. The committee are quite content to leave criticism of this statement in the hands of the public, and especially those of the public who are acquainted with hospital outpatients. They strongly condemn the action of the society in publishing such a paltry accusation without making any effort to verify the statement in one single instance. It savours of the lack of candour and of the prejudice and narrow mind which have characterised the whole of this action.

It now only remains to prominently call attention to a few facts: (a) If the attack of the Medical Society was unprejudiced and promoted in the public interest, it is most extraordinary that every point in favour of the hospital has been deliberately suppressed in the statements sent to THE LANCET. (b) That the Medical Society has avoided and shirked in every possible way every offer from the committee of the Women's Hospital which would have enabled them to have arrived at the real facts of the case. *They would not hear a statement from Mr. Tait and Mr. Eliot on all the operations performed*, still maintaining (or insinuating) that operations were recklessly performed. They would not state any single case in support of these many accusations, although they have been repeatedly urged to do so by the Hospital Committee. (c) That gentlemen who are senior in the profession, and whose opinions are most valuable, have in consequence resigned their membership of the Southampton Medical Society. (d) The committee have only one object in view, and that is in a particular branch of science to bring the highest possible advantages of modern art and surgery within the reach of some of the poorer women in this town. (e) That in no other institution in the neighbourhood could a patient receive the advice of a surgeon of Mr. Tait's special experience.

In conclusion, and reviewing the whole correspondence and actions of the Medical Society, the committee cannot help drawing attention to the opening remarks of Mr. Bullar's first address, in which he carefully defines "professional jealousy" in its "good form" and its "bad form." The committee cannot discover the former—they sincerely hope it is not the latter.

(Signed)

A. F. FORBES, M.A.,
Chairman of the Committee.

H. C. PHILLIPS, Hon. Sec.,
Southampton Women's Hospital.

April 6th, 1895.

* * We have received with the above letter copies of all the documents referred to therein. We cannot assume the position of arbitrator, but it seems to us that both indictment and answer might well have been shorter and more specific and categorical in character.—ED. L.

"SATISFYING (OR NOT) THE EXAMINERS."

To the Editors of THE LANCET.

SIRS,—May I be permitted through your columns to ask the following question? Why is such mystery practised in the results of the examinations of the Royal Colleges of Physicians and Surgeons of England? To illustrate this, a medical student competes for an examination. He fails, and has not the satisfaction of knowing whether his failure is due to the written or oral part of his examination. The information he obtains is, "he has not satisfied the examiners." If such a system as the publication of the marks he had obtained in the several parts of the examination was observed I think the dissatisfaction which now exists would be at an end. Although a candidate is voiceless in the matter, still the Colleges of Physicians and Surgeons would, I should imagine, in reason concede to any system which would tend to advance the welfare of medical students.

I am, Sirs, yours faithfully,

University College Hospital, April, 1895. C. TILBURY FOX.

"THE TITLE OF 'DOCTOR.'"

To the Editors of THE LANCET.

SIRS,—In your impression of the 30th ult. "M.R.C.S. &c." states with reference to my previous communication on this subject: "Whilst entirely agreeing with him [the writer] that assuming the title of 'Doctor' without a degree entitling one to it should be considered infamous conduct 'in a professional respect,' I cannot agree with him as to the deception practised on the public." If "M.R.C.S. &c.," then, agrees with me that no medical practitioner should be allowed to assume the title of "Doctor" "without a degree entitling one to it," how can he reconcile this first position with the subsequent sentence in his letter? "Let all 'M.D.'s be called physicians, and ordinary diplomates 'Doctors'; for, whatever our qualification is, we are 'doctors.' Why should we not be allowed to say so?" Why should not the licentiates be allowed to do what he holds to be "infamous conduct in a professional respect"? The fact is that many of them do so, and do it without challenge from either the General Medical Council or the bodies from which they hold their qualifications. The "deception practised on the public" is to my mind quite clear. When a man practising medicine, surgery, or any of their collateral departments—such as dentistry, &c.—prefixes his name with the style "Dr.," he certainly leads the public to infer that he is in possession of the degree of "doctor of medicine," and whether intended to deceive or not, if the public are naturally led to misapprehend the act is legally construed as criminal. The whole crux of the question lies between an academic distinction and a vulgar appellation. It is the former and not the latter that a gentleman is expected to put on his door-plate or visiting card. I have never instituted an irrelevant comparison between "licentiates" and "doctors" in respect of medical or general culture. This is a matter entirely outside the argument. I do not regard the mere possession of the doctorate degree as any guarantee of either medical or general acquirements, as I know hosts of "doctors" who are as capable of reading Hebrew as they are of translating their diplomas; but if the "licentiates" consider themselves equal in culture and general acquirements to the "doctors," why do they assume a title which they do not possess? Mr. Pike, in the same number of THE LANCET, says that he has repeatedly applied to the Edinburgh College of Physicians for guidance on this matter, and that he has always received the reply that "my legal title as 'licentiate' was that of physician." Then why does he use any other than his "legal title," even if the College of Physicians is weak-kneed enough to connive at his professional use of a distinction to which on his own showing he has no legal claim?

I am, Sirs, yours faithfully,

Glasgow, April 7th, 1895.

D. CAMPBELL BLACK.

To the Editors of THE LANCET.

SIRS,—I fancy that Mr. A. de W. Baker is not well informed on the state of practice in general if he imagines that matters will "tell seriously against the London corporation and schools" unless some device is found for conferring the title of "Doctor." As a matter of fact, I happen to practise in a degenerated London suburb where medical men, not being graduates, one after the other, without the slightest ceremony, confer the title upon themselves, and this in a far more ostentatious fashion than the respective universities would probably care to have their own legitimate titles displayed. Indeed, one gentleman, who resided in the neighbourhood in its palmy and refined times, and who might in vulgar and popular estimation be considered the leading practitioner, I believe, did so from the first. No doubt it may be conceded that on the whole the title is so diversified that it confers more of a social than intellectual distinction. Be this, however, as it may, it is obviously absurd for practitioners, not being graduates, to advance individual claims on purely intellectual lines to a title they do not possess.

I am, Sirs, yours truly,

London, April 9th, 1895.

M.R.C.S.

DISINFECTION OF SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—Dr. Priestley's paper, an abstract of which appeared in THE LANCET of April 6th, is a valuable contribution towards elucidating the advantageous results obtained by

the inunction of scarlet fever cases with the oleusaban eucalyptus oil. His results, obtained from 120 cases treated in the Leicester Fever Hospital, confirm my statements that albuminuria rarely occurred (his cases were as 1 to 10 of those treated in the ordinary way); that desquamation was hastened (his cases were discharged from hospital a week earlier than the others, saving 14s. a case, or £84 on the 120 cases); that there were few or no deaths (his deaths were 1.6 per cent. to 4.3 per cent. in those under other treatment). The cases with suppurative complications were about the same. These, I maintain, are chiefly due to hospital infection by the streptococcus pyogenes, as we get few or none of these cases in private practice whether treated by eucalyptus or not, and therefore this must be taken into consideration when estimating the results of the eucalyptus treatment. I have before stated that in 156 cases treated in their own homes at Bexley there were no suppurative complications; and I think that Dr. Little of Wimbledon stated at the discussion of Dr. Priestley's paper that he had none there, and most of his eucalyptus-treated cases were discharged from hospital at four weeks and all before the fifth week.

Dr. Priestley says that "it would be manifestly unfair to include cases with only initial symptoms—e.g., sickness, headache, and sore-throat," in the treatment. But these are the cases on which the antiseptic treatment has most effect in checking the fever and sequelæ. Used thus early during the initial symptoms the poison is destroyed, or it is deprived of much of its power for mischief. If the inunction is delayed until the rash is fully out the poison has produced those changes in the epithelium and the tissues which lead to complications. The pseudo-scarlatinal cases, where the evidence of infection is confined to the throat, with, in some cases, a slight rash behind the ears for a few hours, are capable of infecting others, as I have witnessed, and should be treated antiseptically. Cases of scarlet fever occur without any rash being observed, as well as small-pox without pustules, or with only two or three, and if it is desired to stop the spread of infection no mild case of this description should be neglected.

The questions to be decided by those who are investigating the treatment by eucalyptus inunction are: 1. Does it check or stop infection? 2. Does it lessen or shorten the fever? 3. Does it shorten the period of desquamation? 4. Does it prevent albuminuria? 5. Does it reduce the number of deaths? I, as well as many others, say it does all this, and it is for its opponents to prove by adequate experience that it does not. The first question is best tested by treating the cases at their own homes without isolation, as I have done, and allowed other children to enter the patient's room unrestricted after he has been inunctioned and the air of the room well saturated with the vapour of the oil.

I am, Sirs, yours faithfully,

Teddington, April 8th, 1895.

J. BRENDON CURGENVEN.

"THE NORMAL PRÆCORDIA IN CHILDHOOD."

To the Editors of THE LANCET.

SIRS,—With reference to the annotation on this subject in your last issue giving the results of Dr. Whitney's observations on the limits of the (superficial) cardiac dullness in children at various ages, I would point out that his conclusions are altogether at variance with the observations of Stürck on 300 healthy children, quoted in your columns by the late Dr. Sturges.¹ Dr. Whitney's principal conclusion is that after the age of seven or eight years the area of dullness becomes enlarged, the upper border rising often to the second left interspace, and the apex beat, originally within the nipple line, falling to its outside. Stürck found, on the other hand, that the area diminished with the child's age, falling between the sixth and twelfth years by the width of a rib, and that the apex beat, which was at first outside the nipple line, became internal to it after the age of six years. Dr. Garrod² has made some tracings of the area of dullness in children, which generally accord with Stürck's conclusions. It is curious that statements so diametrically opposite in their tenour should be put forward by apparently careful observers. As the dimensions of the superficial cardiac dullness depend mainly upon the extent to which the organ is overlapped by the edges of the lungs, it is of essential

¹ THE LANCET, vol. i. 1894, p. 653.

² Brit. Med. Jour., vol. i. 1894, p. 561.

importance that in all instances noted, not only should the heart itself be healthy, but the lungs also should be healthy and of good development and the thorax of normal shape. Inattention to these points may account for some of the discrepancy. In one of Dr. Garrod's cases "physiological albuminuria" was stated to be present; the heart is not generally, in my experience, normal in the subjects of that condition. Dr. Peacock³ has pointed out the influence of full expansion of the lungs, as in those who lead lives of active exertion, in altering the position of the heart. The organ sinks in the chest under these conditions, but it rises, and is small and shallow, in those with weak and ill-developed lungs. It is true that this would apply less in the case of children, yet here also there is much variation in the functional activity of the lungs. Further, in children the existence of the thymus glands furnishes a disturbing element; its gradual atrophy (vanishing at puberty) should allow the edges of the lungs to approach nearer to one another and so diminish the area of cardiac dullness, agreeing thus with Stürck's view. I am inclined to think that, when we take all these circumstances into account, we must admit that there is great variability in the extent of this area in healthy children. As to the site of the apex beat of the heart in childhood, my own limited observation has shown that this is found in very young children to be in or outside the mammary line, and that it travels inward during later childhood to take up the position natural to adult life. This accords with the statements of Stürck and not with those of Dr. Whitney.

I am, Sirs, yours truly,

Finsbury-square, E.C., April 8th, 1895. R. HINGSTON FOX.

THE PRESENT POSITION OF THE OBSTETRICAL SOCIETY OF LONDON.

To the Editors of THE LANCET.

SIRS.—This society was instituted for the promotion of knowledge in all that relates to obstetrics and the diseases of women and children. The laws regulating its affairs were, therefore, drawn up for a scientific society. At the present time the council has launched upon a career of political agitation, acting as the deputy of the Midwives Institute and the Society for the Promotion of Registration for Midwives. As a result, the name of the society and such prestige as it possesses, are being used to foster legislation to which there are very grave objections, and which has not been submitted to the Fellows for their approval. The President, who stated to the House of Commons Committee that "if he was a poor woman he should prefer to be attended by a really well-trained midwife than an overworked doctor," and the Chairman of the Midwives Board, who has publicly stated "that, from his own experience of the enthusiasm that women, as a rule, brought to bear upon the training, a candidate at the end of three months' training would be able to put to shame in a midwifery examination an ordinary medical student of three years' training," are fair examples of the school of thought represented by the large majority on the Council. With such very poor ideas of the knowledge and capacity of the men for whose teaching and training they and their class are responsible it cannot be a matter of astonishment that the rules of the society have been strained to breaking point for the promotion of legislation intended to facilitate the removal of the practice of midwives from the hands of the medical profession, and in fact to place it on the Continental basis.

The question now arises—Is it the wish of the Fellows that the society should be used as a means to further this end? The rules of the society admit of no discussion on the subject except at the annual meeting held in February, and the Council brought forward nothing at this year's meeting of a contentious nature. At the annual meeting every Fellow is summoned by letter, a week's notice being given, and it is quite clear that the business brought forward by the President in his address should have been brought forward by the council on that day. However, stealing a march on those who are opposed to his views on midwives' registration, he takes the field when he is absolute master of the situation. At ordinary meetings of the society and at meetings of the Council he is the sole authority, and although it is quite clear from a perusal of the laws that it was never contemplated that the President

would introduce contentious business into his address, and take up the position of a partisan in a matter of politics, yet he does both, and allowed Dr. Griffith to propose a resolution of an important character at the ordinary meeting in March, in defiance of the spirit of the rules. At the next ordinary meeting, when, after the reading of the minutes, I attempted to call attention to this resolution, the President prevented my doing so, on the ground that my action was against the laws of the society. Now I am informed officially that the only means of testing the feelings of the society upon the important question of its approval of the introduction into the sphere of the society's activity of political questions, and of the action of the President and the council, is by representations to be made to the council by three Fellows that they desire the repeal or alteration of some laws, and it has been suggested to me that the best course to pursue is to send an appeal to the council signed by as many Fellows as possible to summon a special meeting to consider the propriety of the repeal of Chapter XV. of the Laws, which relates to the Board for the Examination of Midwives. Sitting on the council, as I do, I have objected absolutely to the course pursued, because the members of the council were not elected this year by their constituents with any mandate to alter in any way the character and objects of the society, which have always been scientific in character. Moreover, the laws of the society do not admit of any practical check being placed on the action of the council; it is elected upon general and scientific grounds and not upon political basis at all. Under these circumstances I shall be glad to receive as many names of Fellows as possible, and as soon as possible, who desire the repeal of Chapter XV. of the Laws to be considered by the society.

I am, Sirs, your obedient servant,

Hatfield, Herts, April 8th, 1895.

LOVELL DRAGE.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Recent Murder of an old Man and Attempted Murder of a Boy.

THE inquest on the body of the old man, Edward Moyse was resumed and concluded by the city coroner, Mr. T. E. Sampson, yesterday. The case was alluded to in a recent letter. It caused much excitement at the time, in consequence of the critical state of the principal witness and of the circumstance that the perpetrator of the crime was not known. A man has, however, since been arrested by the police, and the coroner's jury yesterday returned against him a verdict of "Wilful murder." The evidence of Mr. Paul showed that the deceased had in all probability been stunned by a blow on the face and killed by subsequent blows with a hatchet or some similar weapon. Dr. Musson, one of the resident medical officers of the Northern Hospital, stated that the boy Needham, when admitted into that institution at an early hour on Feb. 19th, was suffering from shock and loss of blood, and was in a terrified condition when anyone touched him. He had fifteen cuts on the head, six of which extended to the bone, and in three places the skull was fractured. He had also two cuts on the back of the right hand and the left hand was bruised; the upper lip was cut and the right shoulder slightly bruised. The operation of trephining was performed, and the boy recovered sufficiently to be able to identify his assailant. He also gave evidence at the inquest and identified the prisoner (Miller), who was present, as the man who had assaulted him.

Coroners' Inquests and Medical Evidence.

Referring to the leading article in THE LANCET of last week on coroners' inquests, it may be repeated here what has been stated before, that the present city coroner avails himself in all important cases of expert evidence, at the same time the rights of the practitioner first called to the case are always scrupulously respected. In Liverpool the practice used to be to send for the nearest medical practitioner in cases of accident or urgency. Now the hospital ambulance has largely supplanted those gentlemen who would formerly have been called upon to attend such cases, these being now attended by the ambulance surgeon in the first instance and the resident staff afterwards. The present city coroner has expressed regret that the law does not permit him to remunerate medical practitioners for such

³ Reynolds's System of Medicine, vol. iv., pp. 65, 86.

assistance as they may be able to give him in cases where he does not consider it necessary to hold an inquest. If he possessed such power it might reduce materially the number of inquests.

April 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Presentation to Professor Sir William Turner.

LAST week the veteran Professor of Anatomy in Edinburgh University was presented with his portrait in recognition of his services to anatomy and to the University of Edinburgh. The presentation was made in the large theatre in presence of a large number of friends and admirers. Sir James Russell presided. Professor Cunningham, who had acted as secretary to the presentation committee, intimated a large number of apologies and regrets for absence. Sir James Russell, in making the presentation, referred to the valuable services rendered to science by Sir William Turner's work, and also spoke of his invaluable services to the University as an administrator. Many were tied to him personally because of what he had done for them, for the lessons of untiring industry, indomitable perseverance, and clearness of order and method which he had taught them. Sir William Turner, in acknowledging the gift, referred to the time, twenty-eight years ago, when he was appointed to the chair in succession to John Goodsir. In 1854 he had been appointed a demonstrator under Goodsir, and he considered it fortunate that he had been early brought under the influence of a man of such marked personality, vigorous intellect, and so original in his conceptions. He referred to the changes brought about in the University by the Universities Commission, but expressed his unbounded confidence in the Scottish University system. He referred to the work he had had to do as an administrator in the University and said that he thought teaching anatomy was one of the best preparations for a business life, because it tended to make one methodical and orderly in the arrangement of facts and clear and precise in expression. Sir William Mair proposed the vote of thanks to Sir James Russell. The portrait is by Sir George Reid, P.R.S.A., and is acknowledged on all hands to be one of the artist's most successful efforts.

The McEwan Hall.

The McEwan Hall at the new buildings of the Edinburgh University is rapidly approaching completion, and it has been intimated that Mr. McEwan is to make arrangements with the University Court by which the hall may be used by the Lord Provost and magistrates for important civic functions. The hall will accommodate 3000 persons.

Health of Edinburgh.

The epidemic of influenza has practically passed in Edinburgh. Measles is still epidemic, there having been 239 intimations of fresh cases last week; there were also 7 fresh cases of small-pox and 1 death.

Perth.

During the same week the number of deaths at Perth was only 11, showing a mortality rate per 1000 of 18.9. This is the lowest mortality recorded for the week in the eight principal towns in Scotland, the highest being that of Aberdeen, 30.3. One case of diphtheria was registered at Perth and one at Edinburgh, the only towns where this disease made its appearance during the period under mention.

Aberdeen University Buildings Extension.

On account of the contributions coming in so slowly it has been found impossible meantime to carry out the building extension scheme at Marischal College in its entirety. It has accordingly been resolved to drop for the present the proposed block in front. The south and north wings will be finished by towers according to a modified scheme which will require £16,000 to complete. If £10,000 of this be raised otherwise, Mr. Charles Mitchell, LL.D., of Jesmond Towers, Newcastle, will add to his previous generosity by a gift of the balance of £6000, besides £1000 for a clock for the Mitchell Tower. The modified scheme will permit of the natural philosophy classes being, as arranged, located at Marischal College for the benefit of the medical students. It also provides for the widening of Broad-street from Long-

acre to Littlejohn-street and the removal of the Greyfriars Church from its present site. The result will be the throwing open to uninterrupted public view of the quadrangle, including the fine polished granite obelisk in memory of Sir James McGregor—so long connected with the Army Medical Department—and the handsome buildings surrounding the quadrangle, while the new Mitchell Tower will crown the background in an imposing manner. A tender has been accepted for the new electric organ for the Mitchell Graduation Hall, the cost being 1000 guineas. Among additional subscriptions from India just received by the hon. treasurers of the buildings extension scheme may be mentioned: Surgeon-Colonel R. Harvey, £100; Brigade-Surgeon-Lieutenant-Colonel G. A. Maconachie, Malabar Hill, 100 rupees; Dr. G. Watt, C.I.E., 100 rupees; Surgeon-Lieutenant-Colonel R. L. Dutt, 50 rupees; Surgeon-Major S. H. Dantra, 100 rupees; Surgeon-Captain D. M. Davidson, Gurdaspore, 50 rupees; Surgeon-Captain A. Alcock, 100 rupees; and Surgeon-Captain J. Murray, 100 rupees. His Excellency the Viceroy gives 200 rupees, and there are various subscribers in the Civil Service, besides civil engineers and clergymen.

Sad Death of a Young Physician.

It appears that Mr. John Pye Farquharson, M.B., C.M. Aberd., assistant to Dr. Mitchell, New Deer, had been in the habit of reading in bed by candle-light. About three o'clock on the morning of Wednesday, the 3rd inst., Dr. Mitchell, who slept in the room below, was aroused by a moaning sound coming from Dr. Farquharson's room, and proceeding thither found the room full of smoke, the bedclothes smouldering, and its occupant in an unconscious state. Though Dr. Farquharson had no recollection of how it came about, it is clear that he had fallen asleep and by some movement brought the bedclothes in contact with the light. Dr. Farquharson, who was very severely burned, died on the 6th inst. from the effects of his injuries. He was the elder son of Mr. P. Farquharson, a member of the Aberdeen Town Council, and graduated M.B., C.M., at the University of Aberdeen in 1891, and was for a time resident medical officer of Ardwick Provident Dispensary, Manchester. He was well known while a student at Aberdeen as a player of Rugby football, and was exceedingly popular with his classfellows.

Vaccination in Scotland

In the annual report of the Registrar-General for Scotland for 1894 there are contained the statistics of vaccination relating to the children born during 1893. These show that of 127,155 children born in Scotland, 108,117 or 85.028 per cent., were successfully vaccinated. In 2474 cases certificates were granted by medical officers, being at the rate of 1.946 per cent. of the whole births; in 509 cases the children were certified to be insusceptible of vaccination in consequence of some constitutional peculiarity, being at the rate of 0.4 per cent.; 273 children, or 0.215 per cent., were insusceptible from having been vaccinated, but by persons who were not qualified to grant certificates to that effect; and one child was insusceptible from having had small-pox; 12,781 children, or 10.051 per cent. of the whole births, died before vaccination; and 3000 children, or 2.359 per cent., were removed from the district in which they were born before vaccination, or in some other way unaccounted for. It is noted that the proportion of children constitutionally insusceptible and of those who died before vaccination were considerably above the average for the preceding ten years. Further statistics are given showing that of the 114,374 children alive at the age of six months, 108,117, or 94.524 per cent., were successfully vaccinated. These figures are fairly concordant with those of England and Wales, the proportion of the successfully vaccinated being, however, somewhat higher in Scotland. Appended to the statement as to vaccination is an instructive return of the small-pox mortality in Scotland since 1855, including a table showing the ages at death during several periods, the percentages being as follows:—At ages 0 to 5: 1894, 16.81 per cent.; 1885-94, 14.52 per cent.; 1875-84, 20.19 per cent.; 1865-74, 28.41 per cent.; 1855-64, 75.03 per cent. At ages 5 to 20: 1894, 10.62 per cent.; 1885-94, 10.75 per cent.; 1875-84, 25.96 per cent.; 1865-74, 28.96 per cent.; 1855-64, 12.19 per cent. At ages 20 to 60: 1894, 66.37 per cent.; 1885-94, 69.89 per cent.; 1875-84, 52.89 per cent.; 1865-74, 41.54 per cent.; 1855-64, 12.67 per cent. At 60 and above: 1894, 6.2 per cent.; 1885-94, 4.84 per cent.; 1875-84, 0.96 per cent.; 1865-75, 1.09 per cent.; 1855-64, 0.11 per cent. The returns for 1894 are not completed; they comprise only

113 deaths in eight principal towns, but the figures are interesting as showing the notable change in age-incidence of the small-pox deaths in that of the three decades subsequent to the Vaccination Act coming into operation, compared with that of the ten years preceding this (in 1855-64). It will be seen that the relative mortality has shifted from the earlier to the later periods of life in a striking manner.

Caitness County Council is to erect a hospital (twelve beds) in the town of Thurso. As hospital accommodation for rural districts in the county it is proposed to rent suitable houses.

April 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Down District Asylum.

I FIND from the report of the resident medical superintendent, Mr. Nolan, for 1894 that during the year there were 623 cases under treatment. There were 72 discharges and 50 deaths, and there was an excess of 2 males and 79 females over the normal limit of accommodation. The unusually high number of admissions (159), higher than any other since the opening of the asylum in 1889, may be taken not as indicating a proportionate increase of insanity in the county, but as due to the extension of more enlightened views regarding the nature and treatment, rather than as a rapid growth of insanity. There was a history of heredity in 33.3 per cent., but, owing to the very imperfect family histories obtained from the class from whom the patients are drawn, and their natural reticence to give information on such a subject, it may be safely assumed that this percentage is very much under the real number. As asylums are now much more appreciated than formerly it is, although a paradox, a fact, as Mr. Nolan states, that the wiser we grow the more insane will be found in our asylums.

Belfast City and District Lunatic Asylum.

At the monthly meeting of governors, held on April 8th, the resident medical superintendent stated that there were at present in the house 231 males and 137 females over the normal accommodation. The proposed alterations at Purdysburn, when completed, will afford accommodation for 75 male patients, but will give no accommodation for female patients, and, as the County Antrim Asylum will not be ready for at least twelve to eighteen months to come, additional accommodation, even for chronic patients at Purdysburn, would be urgently needed. It was decided to discuss the whole matter of providing for this increase of patients at the next meeting.

The Purdysburn Sewage Scheme.

A very large and important deputation of people in the district of Purdysburn appeared before the Board of Governors on April 8th, to protest against the proposal to carry any of the sewage into the local river. After the deputation had been heard Alderman Graham, M.D. (one of the Governors), who is chairman of the Public Health Committee of the City Council, said he had always disagreed with this sewage scheme, as he condemned all systems, such as the one suggested, of the chemical treatment of sewage as unsatisfactory. What success had been achieved in certain places was only in the way of abating, not of removing the evil. A long discussion followed, and it was stated that the Board of Control had approved of the sewage scheme. Some of the governors thought the best way out of the difficulty would be to pipe the sewage to the city sewers; but this scheme, it was shown, would be most expensive. Finally, it was settled to refer back the whole matter to the committee for further consideration. It is quite evident that the question of what plan to adopt in reference to the sewage of the Purdysburn Asylum will be a most difficult one.

Armagh Sewage Scheme.

The Armagh Town Commissioners having received a sealed order from the Local Government Board to execute certain work with regard to the sewage of that city, have had plans furnished to them by Mr. Peddie, engineer to the Ulster Sanitary Association, for an entirely new system of sewage,

which, I hear, is to provide for disinfection of the sewage on the chemical plan. On April 8th a deputation appeared before the Board urging that if the sewer complained of, and in regard to which the recent investigation was held, was put right the command of the sealed order would be satisfied. They urged that this would be much less expensive than the proposed new scheme. The chairman said that the sealed order went further than the deputation seemed to think. It did not particularise the place complained of, but said that the sewers in the urban sanitary district were to be set right. Even taking the river complained of alone, it would entail a complete renovation of the sewerage of the city. The committee appointed by the commissioners having gone most minutely into the scheme (and most of them were ratepayers themselves), considered that the plan was as cheap as one as could be secured. The report dealing with the site of the sewage works was adopted. As Mr. Peddie had stated there would be no smell from the site of the works, it was decided it should be placed near the city and the expense of carrying it outside the municipal boundary be saved.

The Winter Session at Belfast.

The winter session, both at Queen's College and at Hospital, came to an end on April 11th. The class examinations will be held next week.

The Battle of the Clubs at Cork.

The local papers recently announced that one of the clubs had increased the salary of their recently-appointed medical officer in recognition of the satisfactory manner in which he had discharged his duties. As I do not object to giving further publicity to the generosity of this club, I may mention that a few months ago the members of the club appraised the value of the services of their newly-appointed surgeon at 5s. per annum per member, which sum was to pay for attendance on the members and their families. The club has now—no doubt after mature deliberation—decided on further augmenting the income of their medical officer by presenting him with an additional shilling. It is recognised on all sides that the present comparatively healthy condition of the city is an aid to the clubs in their contest with the local profession, as few consultations are required, and the amount of work thrown on the imported medical men is well below the average. But if much sickness prevailed the exacting members of societies would soon become discontented owing to their limited staff being unable to visit patients at one and the same time in different parts of the city. The numerous communications received by the local committee indicate the widespread interest taken in the movement initiated by the Cork doctors, and I have no doubt a blow will be struck in various other quarters at the tyranny of the clubs. Even a protest has been raised in far-away Fiji. A letter addressed to one of the newspapers published there has been forwarded to us, in which the writer contrasts the action of working men when as employers they are dealing with members of the medical profession and when, on the other hand, they want to exact for themselves increased wages from the "bloated capitalist." I have but one word to add: the Cork doctors are as united and determined as ever.

The Witchcraft Case at Clonmel.

The magisterial inquiry has resulted in the return of seven of the prisoners for trial on the capital charge; but, from the evidence given on the last day of the investigation, it would appear that the presence of some of the prisoners whilst part of the atrocity was being enacted was due to the fact that the husband of the unfortunate woman flourished a knife which he threatened to use. In that way he compelled one of the men to assist him in burying the body, and prior to its removal he stated that as he could not drive out the devil through the chimney he would drive her out through the door. Afterwards he was evidently seized with remorse on becoming convinced that it was really his own wife that he had so cruelly done to death. The charge against the "herb doctor" was dismissed on the ground that he had no connexion with the case further than prescribing for the poor patient.

The Payment of Locum Tenents of Dispensary Medical Officers.

As I have already mentioned, Mr. Blanchard caused his solicitor to write to the Middleton Poor-law guardians threatening legal proceedings in case they should persevere in refusing to pay him for discharging the duties of one of the dispensing medical officers during the absence of the latter

owing to ill-health. The important question raised was as to whether the guardians or their medical officer should be held responsible to Mr. Blanchard for his fees. The Local Government Board have now decided that the guardians should pay, and this decision will of course rule many other similar cases.

Veterinary College for Dublin.

The preliminary arrangements for the projected veterinary college in Dublin are now well advanced, and the terms of the charter are being considered by the legal authorities. The next important step will be the introduction of a Bill dealing with the financial question.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Diagnosis of Diphtheria.

SINCE the important communication of Dr. Roux at Budapest was made, I, doubtless in common with a good many of my confrères, made it a matter of routine to determine bacteriologically the nature of any affection of the throat characterised by a secretion deposited on the tonsils. Hitherto it has only been at the laboratory of the enterprising journal, *La Presse Médicale*, that the gratuitous diagnosis of these cases has been possible in Paris, although some capable druggists undertake the task at a moderate price. This lacuna in the arrangements for the prompt tackling of diphtheria has induced the municipal council to create a special department for this purpose at the Laboratory of Micrography of the city of Paris, in the Montsouris Observatory. Here the practitioner will be supplied on application with tubes of gelatinised serum and a spatula for the preparation of the culture at the bedside. The tube returned to the laboratory, the result will be transmitted to the medical man within twenty-four hours. The sum of 10,000 fr. was on April 6th voted towards this laudable object.

Student Soldiers.

It has always been a matter of surprise that the energies of the medical recruit should be wasted on drills and exercises of a purely military character, and that his special knowledge should not rather be utilised in the hospital wards during his term of service. This blid policy was more to be wondered at when it was a matter of common knowledge that, on the outbreak of war, the supply of surgeons would inevitably fall far short of the demand. The present Minister of War has appreciated the incongruity, and has consequently just decided that, after having undergone a short course of instruction in soldiering, student-recruits will in future be employed as *infirmiers* in the wards. Students have cause to rejoice at this sensible decision, for the application of the new regulation will necessarily keep them more in touch with their future occupations, and render their presence in the ranks less a waste of time, from a medical point of view, than has hitherto been the case.

A Monument to the late Professor Villemain.

On Sunday, the 31st ult., there was unveiled in the Cour Boussais, at the Val-de-Grâce Military Medical School, a statue of the late Dr. Villemain, known to the profession for his remarkable researches into the nature of tuberculosis. The Minister of War was represented by Dr. Colin, *Inspecteur-Général du Service de Santé*, and all the available members of the *Corps de Santé* were present, as well as the students of the Val-de-Grâce and such civilian practitioners as MM. Berger, Landouzy, Hanot, Perrier, Herard, &c. Discourses were delivered by Dr. du Cazal, *médecin-principal*, and Dr. Colin, the latter observing in the course of his remarks that the army surgeon should never forget that he is the chief consoler of the soldier serving far away from his home.

The late Professor Georges Pouchet.

The late regretted Professor of Comparative Anatomy at the Muséum d'Histoire Naturelle, who died on March 29th of last year, and was buried at Père-Lachaise, had gathered round his grave last week a few sorrowing friends come to witness the unveiling of a monumental souvenir of a great savant. Two brief discourses were delivered, one being by Dr. Dumontpallier, vice-president of the Société de Biologie, to which corporation the deceased left all his fortune.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Rare Diseases of Joints.

AT the last meeting of the Vienna Medical Society Professor Kolisko described some rare diseases of the joints. Syphilitic disease of the joints may be either acute or chronic, the former condition being characterised by serous effusion into the articulation and by inflammatory appearances. He exhibited the knee-joint of a man whose leg had been amputated. The patient's mother had been infected during her pregnancy; he himself has always been healthy, and was the father of healthy children. The joint was ankylosed, the articular surfaces being grown together, with the exception of some narrow spaces. The central parts of the femur were eroded and permeated by a white callus. The surface of this bone was also covered by a layer of osseous substance, which was specially indicative of syphilis. Professor Kolisko describes the following characteristic marks of joint affections associated with tabes: (1) distension of the capsule by serous effusion; (2) proliferations in the synovial membrane; (3) atrophy of the articular extremities; and (4) spontaneous fractures. Contrary to the opinion of French writers, who assume a trophic disturbance, Professor Kolisko explains these processes on the theory that through the insensibility resulting from tabes dorsalis the patient does not feel concussions, and does not fix his joints. If an articulation affected with a neuropathic disease were fixed in an early stage the process could be stopped. French authorities affirm that in spontaneous fractures the bones become porous in consequence of inflammation of their nerves; but Professor Kolisko supposes the incoördination of movement and the want of support from normal muscular action to be the true causes. A third rare disease of the joints is arthritis pauperum, which is very painful, and only attacks the small articulations of the hands and feet of people exposed to privations. The joints are flexed, proliferations occur on the articular extremities, and there may be displacement of the first phalanx on the head of the metacarpal bone.

Death of Dr. Gauster.

By the death of Dr. Gauster, who passed away on March 25th, the profession of medicine in Vienna loses one of its best known members. Born in Vienna about sixty-eight years ago, he studied at the School of Medicine there, and eventually adopted lunacy as his special subject. Immediately on obtaining his diploma, in 1851, he became assistant director of the Lunatic Asylum of Lower Austria, and in 1888, Professor Schlager having died, he was appointed director. In the fulfilment of his responsible duties he gained universal esteem. His principal works were: *Moral Insanity*, 1879; *Mental Degenerations*, and the *Influenza Epidemic in the Vienna Lunatic Asylum in 1889-90*, and its *Influence on Phrenopathics*. He was also on the Council of Hygiene. Dr. Gauster succumbed to an attack of pneumonia. The funeral took place on March 28th, and was attended by a large gathering of Vienna medical men.

Blindness caused by a Vermifuge.

Dr. Gross¹ relates the following case. A man aged forty-four years after a dose of castor-oil took thirty-two capsules of a vermifuge. In the evening he fainted away, and when admitted to the hospital was found to be suffering from mydriasis and total want of light perception, but without visible change in the fundus oculi. Symptoms of atrophy of the optic nerve subsequently appeared. Each capsule contained ethereal extract of male fern and pomegranate root bark, of each 0.25 gramme (4 grains). Dr. Gross recommends calomel given in half-gramme doses (= 7½ grains) as far the most satisfactory of all the numerous remedies proposed for tænia solium.

The Otological Society.

The inaugural meeting of this society took place on March 28th. Its purpose is the promotion of aural surgery by means of scientific reports, demonstrations, discussions at the meetings, and an annual congress. Professor Josef Gruber was elected president; Professor Pollitzer, vice-president; Professor Urbantschitsch, manager; and Dr. Pollak, secretary.

April 7th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Patrons of Industry and the Ontario Medical Act.

As indicated some months ago, this new political party proposed to introduce a measure which would greatly alter the existing law regarding the practising of medicine in this province. That they have been true to their promise is quite evident from the Bill presented to the Legislature on March 8th last, whilst for brevity it is to be commended, being composed of only eighteen sections; yet for a measure to lay before a House it seems but the offspring of ignorance, and as a result iniquitous. The Ontario Medical Act as at present in the Revised Statutes is the result of legislation at different times since 1850, and has been considered as good a Medical Act as can be found in any country, and now this particular political party, pursuing a destructive course, apparently aims at free trade in medicine. As an example of the destructive process, Section 3 reads: "Sections 17, 18, 20, 23, 25, 26, 27, 30, 31, 33, 34, 35, 36, 37, and 38 of the said Act (the Ontario Medical Act) are repealed." Section 4 is somewhat like it, and refers to the Act of 1891: "Sections 1, 3, 4, 5, 6, 7, and 8 of the Act passed in the fifty-fourth year of Her Majesty's reign are repealed." The purport of the proposed legislation is to take away the powers at present possessed by the Medical Council to control examination and registration, handing them over to the Government under the Department of Education, all fees from examinations to be funded with the provincial treasurer. The Board of Medical Education is to consist of three members of the Medical Council, one representative of each medical school, two homeopaths, and two appointed by the Government, and the fee for registration is placed at the figure most suited to the farmer's pocket—viz., \$5 or £1. The power of removal of name from the Roll is taken from the Council and vested in the senior county court judge. "Unworthy conduct" includes fraudulent advertising, habitual drunkenness, transmission of contagion or infection, or any violation of the Public Health Act, the issuing of false or blank death certificates, neglect to register births and deaths, conviction in any action for damages from injury, and negligence, ignorance, or want of skill. The time of limitation for malpractice is extended from one to two years. Section 16 relates to the licensing of midwives, and is in keeping with the other clauses of the Act. It is sought to license any woman of "good character" who proves by evidence "taken on oath before" any local board of health "that she has successfully performed the office of midwife in at least ten cases of confinement"; she shall on payment of the nominal fee of 4s. 2d. to the treasurer of the municipality be licensed to practise midwifery in the municipality for two years. The framer of the Bill has added the words, renewable upon "the production of similar evidence of good character." The licensed (!) modern "Sairy Gamps" are to be protected from the penalty for practising without registration and for falsely pretending, a proviso which I think entirely nullifies the provisions for licensing. The measure virtually permits the practice of midwifery by any woman. Sufficient has been stated of this Bill to indicate the manner the "Patrons of Industry," who claim to represent the farming community, wish to treat the practice of medicine in Ontario.

Provincial Expenditure on Hospitals &c.

Last year the revenue derived from succession duties was applied to the maintenance of hospitals and charities. The estimated revenue was \$70,000, whilst the actual amount received was over \$150,000, being only \$40,000 short of the amount actually expended on these institutions. The provincial treasurer, in his Budget speech, stated that he hoped in the near future the revenue from the succession duties would cover the grants under this head.

Insane Asylums in Ontario.

The seven institutions of the province have accommodation for 4586 patients. On Dec. 31st, 1894, there were 4441 inmates. That the service is efficient no one denies, that cost of management is kept at a low figure is a fact, but I cannot but notice that the Government are receiving medical services of a high quality at a figure much below that usually paid on this continent, and I venture to say that the salaries of those in this particular service might be increased without a charge being made of "high salaries."

It would appear that the Government make a boast of paying low salaries to professional employés, for the Budget states that, whilst the cost *per capita* for medical service in New York State is \$14.34, yet in the province it is only \$5.33. In the case of employés the comparison is not so great, being \$70.63 in New York to \$32.17 in Ontario, and the cost per inmate in the adjoining State is \$184.77 to \$127.32 with us, the difference of salaries paid to the medical staffs being nearly \$40,000.

Insurance Murders.

Public attention has for the past few weeks been directed to several cases of this class. In one in the western portion of the province the deceased was found under a fallen tree, it being claimed that death was due to the blow received from the falling tree; there had recently been over £6000 of insurance placed upon the victim's life. As a result of the inquest two persons were committed, charged with the murder, both being found guilty at the assize and sentenced to be hanged, since which one has confessed that they first killed their victim with an axe, placing subsequently the body under the fallen tree. The second case is more complicated, owing to the deed with which two are charged having taken place nearly three years ago in Toronto. A young man upon whose life there was a large insurance was supposed to have been accidentally killed by the weight (200 lb.) of a hoist having fallen and crushed his skull. Suspicion was not aroused until insurance was sought for—some £60,000—upon his sister's life, who in the meantime had married one of two brothers in whose warehouse the supposed accident happened. The body has been exhumed, and the evidence of the medical experts at the preliminary investigation is alleged to show that the injuries to the skull were not caused by the hoist weight. The two brothers are now awaiting trial on a charge of murder.

Toronto.

Obituary.

JAMES HARMER SOMERVILLE, M.R.C.S. ENG., L.S.A.

THE announcement of the death of Mr. Somerville has caused profound sorrow in Bloxwich and the adjoining parts of the county of Stafford, where his family had long been domiciled, and where he himself had for many years in his professional capacity enjoyed the confidence and esteem of all ranks of society. His father, the late Mr. James Somerville, was a well-known practitioner in the district, and was in due course succeeded by his son, who gained the diploma of the Royal College of Surgeons of England in 1861 and that of the Society of Apothecaries in 1863. Activity and energy were the distinguishing features of Mr. Somerville's character. He acquired some prominence in the local political organisations, and delighted in outdoor sports as long as his strength permitted. Latterly, however, his health declined, and, though not more than fifty-five years of age, he found his strength unequal to the fatigues of his extensive practice. It was hoped that a visit to Hastings would be beneficial, but a residence there of some weeks did not produce the desired result, and the end came peacefully on March 28th. The funeral took place at Bloxwich churchyard on April 1st, and was attended by a very large gathering of sympathising friends and by a company of the 2nd Battalion South Staffordshire Regiment of Volunteers, to which the deceased was assistant surgeon. Mr. Somerville was twice married and is survived by his widow. His eldest son resides in Walsall.

JOHN REEKS, M.R.C.S. ENG., L.S.A.

THE announcement of the death of Mr. John Reeks, which took place at his residence at Southwick, Sussex, on April 5th, was received with profound regret by his friends and patients. Mr. Reeks had an attack of influenza some three or four weeks ago, from which he really never recovered. Born at Elcott, in Berkshire, he was educated at Newbury, in the same shire. In 1879 he went to St. Bartholomew's Hospital, where he gained the degrees of M.R.C.S. Eng. and L.S.A. in 1884. For some time he was the assistant medical officer at the small-pox camp at Darenth, and was in practice for several years at Forest Gate. In 1887 he went to Southwick,

succeeding the late Mr. Nathaniel Jarvis. Mr. Reeks was most popular in the district, where he had an extensive practice, and his demise leaves a notable blank in local society.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. Moritz Gauster, Director of the Lower Austria Insane Asylum. The most notable of his earlier papers, while he was district medical officer in Stein, was one on the Infection of Human Subjects by Anthrax. This attracted the attention of the Government, and he was called to Vienna and appointed member of the Medical Council. He took a great interest in popularising hygienic knowledge and wrote a manual on this subject for schoolmasters. He also published a good many papers in professional journals and annuals on Mental Disease, especially on its connexion with Alcoholism and Influenza.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated:—

Wednesday, April 3rd:—

Anatomy and Physiology.—Lawrie Hugh McGavin, Joseph Elford Dupigny, and Hereward Evelyn Croker Fox, students of Guy's Hospital; Matthew Henry Gregson Fell and Richard Harte Lloyd, St. Bartholomew's Hospital; Ernest Charles Lambert and Walter Biscoe Silas, Westminster Hospital; John Charlton Briscoe, George Augustus Roberts, Colton Taylor Lewis, and Frederick Augustus Hadley, King's College, London; Harold Douglas Singer, St. Thomas's Hospital; Frank Atthill and Harold Arthur Thomas Fairbank, Charing-cross Hospital; Harold Shuttleworth Barwell, St. George's Hospital; Thomas Henderson Dugon, London Hospital; George Baynton Forge, London Hospital and Mr. Cooke's School of Anatomy and Physiology.

Anatomy only.—Mr. George Fernandez Mitchell Clarke, Charing-cross Hospital. Nineteen gentlemen were referred in both subjects and two in anatomy only.

Thursday, April 4th:—

Anatomy and Physiology.—Joseph Arthur Mawson, Yorkshire College, Leeds; Gilbert Bahn Thwaites, Bertram Mitchell Young, and John Francis McLean, St. Thomas's Hospital; Parkinson Osborne Gruber, St. Bartholomew's Hospital; William Ellis Morgan, Charing-cross Hospital; Theodore Marles-Thomas, John Llewelyn Jones, and Campbell Dykes, University College, London; Henry Neville Coltart, St. George's Hospital; George Louis Atkinson and Thomas Hudson Gardner, King's College, London; Arthur Trevor Richardson-Jones, Oxford University and King's College, London; Harold Sugden Crapper, Guy's Hospital; Robert McKay, Middlesex Hospital; John Mayor Wilson, Middlesex Hospital and Royal College of Surgeons, Edinburgh; Hillel Jacob Farhi, Syrian Protestant College, Beyrut, and London Hospital; and Wilfred Joseph Lubeck, Medical College and University, Madras.

Anatomy only.—Martin Clover, University College, London. *Physiology only.*—Thomas Howard Body, Guy's Hospital; and Frederick Arthur Johns, London Hospital.

Fourteen gentlemen were referred in both subjects, two in anatomy, and two in physiology.

Friday, April 5th:—

Anatomy and Physiology.—Stanley William Randolph Colyer, Charing-cross Hospital; Frank Poarac Bond, Westminster Hospital; William Taylor Milton, Philip Turner, Charles Leopold Granville Chapman, Robert Fell, Septimus Benjamin Cullen Carter Adolphus Pennington and Thomas Percival Berry, Guy's Hospital; David Samuel Robert Halstead Dixon, Edmund Howard Barrett, and Alexander Stoker Gardiner, St. Mary's Hospital; William Trethowan Rowe and Robert Raines, St. Bartholomew's Hospital; John Alfred Barnes, John Ellis Kilvert, and Thomas Hoban, St. Thomas's Hospital; Montague Dixon and Percy Glyn Savours Williams, University College, London; Walter Biggar Bannerman and Ralph Norman, London Hospital.

Anatomy only.—Harold Charles Harrison, St. Bartholomew's Hospital; and Ernest Urquhart Bartholomew, Charing-cross Hospital. Thirteen gentlemen were referred in both subjects, and one in anatomy only.

Monday, April 8th:—

Anatomy and Physiology.—Robert Craker Leaning, Harold Dyer, Frank Charles Lewis, and Frank Sherwill Dawe, St. Mary's Hospital; Seymour Alfred Millen and William Christopher Long, St. Bartholomew's Hospital; Frederick Edward Walker, Francis John Hensley Martin, Walter Henry Maxwell Telling, Francis Harold Rodier Heath, Herbert Melbourne Berncastle, Arthur Ernest Clarke, and Eugene Gilbert Goldard, Guy's Hospital; Sydney Oliphant Bingham, Henry Harold Scott, and Edward Alfred Gates, St. Thomas's Hospital; Humphry Morshead Hart-Smith, Cambridge University and University College, London; Carol Luther Betteson, Cyprian Royston Pike, George Heywood Herbert, and Clement Woodthorpe Chaplin, London Hospital; Arthur Martin-Leake, University College, London; Edward Protheroe Smith and Leslie Milburn, Middlesex Hospital.

Twelve gentlemen were referred in both subjects.

Tuesday, April 9th:—

Anatomy and Physiology.—Shaik Abdur Ruzzak, Herbert Lightfoot Eason, Alfred Cole Ambrose, and William Mussellwhite, Guy's Hospital; Angus Joseph McNab Cudden-Fletcher, St. Bartholomew's Hospital; Ralph Albert Rogers Lankester, University College Hospital; George Wiun and Irwin Walker William Hunter, London Hospital; Thomas Jones, Arthur Ernest Relph, and George Humphry Lucas, Middlesex Hospital; and Alexander Fleming Millar, St. Thomas's Hospital.

Anatomy only.—Alfred Edward Seller and John Maclean Carvell, of London Hospital; Charles Walter Gibson, of Guy's Hospital; Philip Phillips, of Charing-cross Hospital; and Albert Ernest Street, of Charing-cross Hospital, and Mr. Cooke's School of Anatomy and Physiology.

Physiology only.—Frank Howard Lawson, of Middlesex Hospital; Nicolas Buendia, of University of Colombia, and Cecil Edward Andrews, of London Hospital.

Thirteen gentlemen were referred in both subjects, five in anatomy, and five in physiology only.

UNIVERSITY OF GLASGOW.—The following have passed the first professional examination (old regulations) for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

Thomas Small Goodwin, Charles David Picken, Alex. J. T. Swann, and Ernest M. Watkins.

The following have passed the first professional examination (new regulations) for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated after their respective names (B., Botany; Z., Zoology; P., Physics; C., Chemistry):—

James Napier Baxter (B., P.), James Freeborn Bennett (Z., C.), William Bennett (B.), William Broad (B., Z., C.), Andrew Brownlie (P.), John Brunton (B., P.), Thomas Bullough Calland (B., C.), Ronald Douglas Campbell (P., C.), James Carruthers, M.A. (P.), Alexander Henderson Cassells (Z., C.), James Robert Chalmers (Z., C.), Andrew Clark (B.), David Macleure Cowan (Z., C.), George Morris Crawford (B., P.), John Cullen (P., C.), Charles Cheven Cumming (Z., P.), Archibald William Wallace Davidson (Z., P.), David William Davidson (Z., C.), John Lithgow Davey (B., P.), James Dick (Z., P.), James Austin Dickie (Z., P.), Frank Lindsay Dickson (Z.), James Drummond (P., C.), Comyn MacGregor Finlay (Z., P.), Matthew Wm. Fraser (Z., P.), John Andrew Garden (B., P.), John Gracie (B., P.), George Henry Fullarton Graves (Z.), Archibald Wilson Harrington (Z., P.), Leslie Charles Broughton Head (Z., P.), John Henderson (C.), Isaac Mackay Huey (Z., P., C.), Thomas Inglis (Z.), Robert Dallas Kennedy (B., P.), Andrew Kerr (Z., P.), David Littlejohn (B., C.), James Grant Milner (Z., P.), Ramsay Millar (Z., P.), Hugh Miller (P.), Norman Macleod Miller (Z., P.), Alexander MacCulloch (B., C.), James Hogg Macdonald (Z., P.), Archibald Turner Macewan (P., C.), Peter Macintosh M'Fadyen (Z., P.), John M'Gillchrist (Z., P.), David Duncan Fraser Macintyre (B., P.), Charles Forbes Maclean (Z., P.), Norman Forbes MacLeod (Z., P.), William Johnston Macleure (B., P.), Alfred Robert MacLurkin (Z., C.), John M'Millan (B., P.), Roderick Reid Macnicol, M.A. (C.), Thomas Neill (B., P.), John Patton (B., Z., C.), Thomas Stephens Picken (Z., P.), William Barr Inglis Pollock (B., P.), Arthur Robin (Z., P.), James Scott, M.A. (Z., C.), John Shaw, M.A. (Z., C.), James Shearer (B., Z., P., C.), Andrew James Smith (Z., P.), David James Smith (Z., P.), James Smith (P., C.), James Johnston Smith (B., C.), William Stewart Stalker (P., C.), Alfred George Stewart (Z., C.), Frederick Richardson Stewart (B., C.), James Douglas Brownlee Stewart (B., C.), Peter Donald Strachan, M.A. (B., C.), James Alexander Sutherland (B., P.), Charles Pinkerton Thomson (Z.), William Brown Thomson (B., P.), Thomas Bird Tierney (P., C.), Alexander Laurie Watson, M.A. (Z., P.), Alexander Simpson Wells (Z., C.), Robert Orr Whyte (B., Z., P., C.), George Henry Wildish (Z., P.), Morgan Watkin Williams (P.), Alexander Wilson (Z., P.), William Wright (Z., P.) and John Doctor Young (Z., C.).

Women candidates.—Sarah Davidson (P., C.), Marjorie King Henderson Fleming (P., C.), Jessie Downie Granger (P., C.), Mabel Hardie (P., C.), Jessie Sophia Beatrix Hunter (P., C.), Mary Longmire (B., P.), Jane Lorimer (C.), Annie Louise M'Ilroy (B., C.), Ina Lochhead M'Neill (P., C.), Mary Lauchline M'Neill (Z., P.), Sara Maude Robertson (P., C.), Maud Spencer (P., C.), Gertrude Florence Fleetwood Taylor (P.), and Grace Lorrain Young (P., C.).

The following have passed the Second Professional Examination (old regulations) for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

William Buchan Armstrong, John Tait Bowie, John Ritchie Burns, James Banks Cumming, John James Edgar, George Louis Le Fèvre, Robert Hugh Meikle, John Allan Craigie Macewan, William Fullerton M'Even, Archibald M'Glashan, Lionel Mitchell Mackay, William M'Mullen Pearson, James Hood Rankin, James Rutherford Ratcliffe, Robert Shanks, Joseph Sillars, Archibald Stevenson, and David Lyon Stevenson, M.A.

The following have passed the Second Professional Examination (new regulations) for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated after their respective names (A., Anatomy; P., Physiology; M.M. and T., Materia Medica and Therapeutics):—

Alexander Smith Allan (A., P.), Theodore Belchambers Broadway (A., P.), David Louis Cairns (A., P.), Francis James Charteris (A., P.), Joseph Adam Clarke (A., P.), George William Coats (A., P.), James Duncan Cochran (A., P.), Walter Scobie Findlay, M.A. (A., P.), James Finlayson Fleming (A., P.), Adrian Andrew Forrester (A., P.), Lawrence Whitaker Harrison (A., P., M.M. and T.), Alexander Lawrie (A.), William Mitchell Lindsay (A., P., M.M. and T.), William Glen Liston (A., P., M.M. and T.), John MacDonald (A., P.), James M'Haffie (A., P.), David M'Kail (A., P.), James M'Queen, M.A.

(A., P.), Normal Emil Henry Scott (A., P.), Alexander Bankier Sloan (A., P.), Samuel Macfarlane Sloan (A., P.), David Steele Smith (A., P.), James Strong (A., P.), Matthew Logan Taylor (A., P.), Walter Lewis Thomson (A., P.), William Watson (A., P.), Ernest Watt (A., P.), Edward Roberts Weir (A., P.), William Wyper (A., P.), and David John Young (A., P.).

Women candidates.—Daisy Annabella Murdoch Clark (A., P.), Margaret Elizabeth McNeill (A., P.), and Jessie Hawkesworth Smith (A., P.).

The following have passed the third professional examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

A., including Pathology.—John Allan, Samuel Anderson, B.Sc., John Ritchie Brown, William Burns, Malcolm Campbell, John Divine, Matthew Dunning, Thomas McGibbin Fletcher, Daniel McIntyre Glen, George Hanson, Allen Iredale, John William Jackson, John Knight, John Walker Munro, William Milroy McFarlane, John Souttar McKendrick, Hugh McLaren, John McLaws, Thomas Duncan Newbigging, Harry Couper Patrick, David Shedden Service, James Craik Taylor, Noel Charles Echlinz Ward, Henry Whitehouse, and James Eric Wilson.

Women candidates.—Mary Baird Hannay and Madge Speirs Maclean. *B., not including Pathology.*—Alfred Charlton, Duncan Drummond, George Henry Beck Harvie, Robert Hastie, James Hogg, Edwin Brooke Jago, John Marshall, Samuel Martyn, John Robert Gordon Phillips, James Malloch Robertson, Neil Robson, Wm. Kerr Russell, and Ernest Fred. Doctetti Walker.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—

SCHOOLS OF SURGERY.—Class prizes winter session, 1894-95. Descriptive Anatomy: Junior, W. J. Anglim, first; H. M. Clarke and J. M. Crawford (equal), second; senior, F. J. Palmer, first, and R. H. D. Pope, second. Practical Anatomy: First year, S. R. Godkin, first, and J. J. Huston, second; second year, M. W. Falkner, first, D. Hadden and J. Leventon (equal), second; third year, A. S. Greeze, first, and A. McMunn, second. Practice of Medicine: D. Kennedy, first, and W. M. Power, second. Theoretical Surgery: A. I. Eades, first, and D. Kennedy, second. Midwifery: G. A. Robinson, first, and J. A. McMunn, second. Physiology: F. J. Palmer, first, and D. Hadden, second. Chemistry: W. J. Anglim, first, and S. R. Godkin, second. Pathology: G. A. Robinson, first. Physics: W. J. Anglim and D. A. Fitzgerald (equal), first, and M. Gavin, second. The schools opened on Monday, April 1st, for the three months' courses of Operative Surgery, Practical Chemistry, Pharmacy, Public Health, Forensic Medicine, Materia Medica, Histology, Biology, and Dissections.

SOCIETY FOR THE PREVENTION OF HYDROPHOBIA AND REFORM OF THE DOG LAWS.—A meeting of the General Committee of the Society for the Prevention of Hydrophobia was held on the 8th inst. at 25, Cavendish-square, W., Professor Victor Horsley, F.R.S., in the chair. In the chairman's report reference was made to the communications which had passed between the Board of Agriculture and the society's executive on the subject of the Dogs Bill, and also to the prevailing epidemic of rabies and hydrophobia in Yorkshire, Lancashire, and other northern counties and in Ireland. It was pointed out that but for political considerations the policy advocated by the society and endorsed by the highest medical authorities, as well as by many of the most important dog-breeders and dog-owners throughout the country, would doubtless be carried into effect by the Government of the day. It would only be when the pressure of these combined forces of instructed and responsible opinion became too great for any Government safely to resist that the object for which the society was formed would be accomplished. This object, it was needless to say, was the total extinction of rabies and hydrophobia from the United Kingdom by a system of universal muzzling for at least twelve months, coupled with rigid and permanent quarantine. The attitude of the general public, except during the scare created by an epidemic of rabies, was one of apathy and indifference. It was useless therefore to expect the assistance which many causes derive from a public movement or demonstration in their favour. The aims the society had in view would therefore be best promoted by securing the increased adherence of members of the medical profession and men of influence generally (especially of those recognised as leaders of opinion in canine matters), so that when the proper moment arrived the society would have sufficient support behind it to convince any Government that the subject was not a question of party politics, but of public welfare. Since the last meeting of the committee liberal contributions to the funds of the society have been received from the Duke of Northumberland (president of the society), the Duke of Westminster, the Earl of Coventry, Sir Joseph Lister, Bart., Sir James Whitehead, Bart., and many others.

PUBLIC BATHS IN SOUTHWARK.—The vestry of the parish of St. Saviour, Southwark, have erected public baths and wash-houses in Lavington-street, at a cost of £40,000, inclusive of £10,000 for the site. There are two swimming baths, the first-class, which is 120 ft. long by 48 ft. wide, and the second-class, which is rather smaller. There are also first and second-class private baths, and in the wash-houses separate compartments are provided for twenty-four workers. The formal opening took place on April 6th, in presence of a large company.

NORTH RIDING INFIRMARY, MIDDLESBROUGH.—The annual meeting of this hospital was held on April 4th, Alderman J. F. Wilson, J.P., presiding. The report showed that there had been a considerable increase in the number of in-patients, and that the expenditure had exceeded the income by £108. Adding the deficiency brought forward from the previous year, the total indebtedness is £252, for the diminution of which special efforts are being made by public appeals and by an exhibition to be held in the town hall in the autumn. There is great need for a new operating room, the estimated cost of which is £900.

CIVIL RIGHTS DEFENCE COMMITTEE (PRESIDENT, THE RIGHT HON. THE EARL OF STAMFORD).—The Committee append a further list of subscribers to the Anderson Privy Council Appeal Fund. At the meeting of the Committee on March 15th, 1895, the following resolution, moved by General Graham and seconded by Mr. Foulerton, was unanimously adopted: "That the thanks of the Civil Rights Defence Committee are due and are hereby tendered to Dr. Branch and the members of the Leewards Branch of the British Medical Association for their generous and practically unanimous support to this committee in the defence of the civil rights involved in Mr. Anderson's case and for their support and sympathy with Mr. Anderson in his arduous and protracted struggle for the defence of these rights. That such support, coming from the West Indies, where the attack upon those rights occurred, is of special value, and is especially appreciated by the committee." Additional subscribers to the Anderson Privy Council Appeal Fund to March 31st, 1895:—

Anonymous sympathiser, per Mr. A. M. Lee	£1 1 0
Dr. Dukes, Rugby, as per list—	
Mr. T. Duke, M.A., Rugby	£0 5 0
Mr. Sutton Pratt, Rugby	0 5 0
Mr. Bernard Belton, Rugby	0 5 0
Mr. W. A. E. Waller, Rugby	0 5 0
Dr. J. H. Simpson, Rugby	0 10 6
Mr. W. G. Groves, Woodford Green	1 10 6
Members of the Leeward Islands Branch of the British Medical Association (collected by Dr. W. J. Branch, St. Kitts)—	0 5 0
Mr. J. D. Bell, Nevis	0 10 0
Dr. W. J. Branch, St. Kitts	1 1 4
Dr. J. H. Cooke, Nevis	0 10 0
Mr. M. P. Duke, Montserrat	0 10 6
Mr. A. E. Edwards, Antigua	0 10 6
Mr. W. H. Edwards, Antigua	1 1 0
Mr. J. Foreman, St. Kitts	0 10 6
Dr. F. J. Freeman, Antigua	0 10 6
Mr. W. H. Fretz, St. Kitts	1 0 10
Mr. J. S. Gabriel, Antigua	0 10 6
Dr. P. J. Huggins, Nevis	0 10 0
Dr. G. H. Mapleton, St. Kitts	1 0 10
Dr. H. A. Nicholls, Dominica	1 1 0
Dr. F. L. Norris, Montserrat	0 10 6
Mr. J. N. Rat, St. Kitts	0 10 6
Mr. R. E. Semper, St. Kitts	0 10 6
Mr. A. L. Wykeham, Antigua	1 1 0

12 0 0

It is particularly requested that all subscriptions to the present fund be sent direct to the Manager of the Union Bank of London (Chancery-lane Branch) and be made payable to the "Anderson Appeal Fund Account."

THE REMUNERATION OF DISTRICT MEDICAL OFFICERS IN WALSHALL.—The sick poor of Walsall are likely to be the gainers by the settlement of a question at issue between the board of guardians and one of their medical officers. This gentleman, having stated that he was unable without assistance satisfactorily to fulfil the duties of his office, the finance committee of the board recommended that a grant of £15 be made to him for cab hire in urgent cases. This proposal of the committee was not endorsed by the board, but at a subsequent meeting held last week when counsels prevailed, and the advocates of economy made a tardy retreat from their indefensible position. Dr. McKinstrey is to be commended for the firmness of his attitude under the circumstances.

LITERARY INTELLIGENCE.—Mr. Lewis will issue immediately in his "Practical Series" a new volume on *Surgical Diseases of Children*, by Mr. D'Arcy Power, M.A., M.B. Oxon., F.R.C.S. Eng.

THE METROPOLITAN HOSPITAL.—The annual meeting of this hospital was held on April 8th on the premises in Kingsland-road, Mr. Joseph Fry presiding. The report showed that 781 in-patients were admitted during 1894, and that there were 78,000 attendances of out-patients. Special arrangements have been made for the attendance of Jewish out-patients on two days of the week, and two wards have been set apart for Jewish in-patients, providing beds for seven men and five women. The hospital dinner will be held on June 13th, and Mr. Leopold de Rothschild has promised to preside.

COOKERY AND FOOD EXHIBITION.—His Serene Highness General Prince Edward of Saxe-Weimar, K.C.B., has consented to open the Eighth Universal Cookery and Food Exhibition to be held at the Portman Rooms on May 7th. The soldier cooks of the Grenadier, Coldstream, and Scots Guards will be allowed, by special permission of the Commander-in-Chief, to take part in the competitions, and the Army School of Cookery, Aldershot, by permission of the general officer commanding, will demonstrate the methods of cooking army rations.

FOOTBALL CASUALTIES.—On the 28th ult., during a match at Brentford between the Brentford Early Closing Association and the North London Wanderers Club, one of the visiting team fractured his leg and was taken to the Brentford Cottage Hospital. On Saturday last the captain of the Scarborough Ebor (Association) Club, while playing for his club, sustained a fracture of his left leg. On the same day a young man aged twenty-two years, in a match between the Radford and Carrington Evening Continuation School teams, fractured his leg and was admitted to the Nottingham General Hospital.

CAMBRIDGE UNIVERSITY.—The following gentlemen have passed the University examination qualifying them for the functions of medical officer of health: William George Armstrong, Martin Ashley, M.B., Frank George Bushnell, M.D., Charles Buttar, M.B., B.S., Allan Gordon Russell Cameron, M.B., B.S., Edgar Godfrey Carpenter, John William Henry Eyre, M.B., B.S., Andrew Mearns Fraser, M.B., M.S., John William Frank Jewell, M.B., B.S., Harold Jossé Johnson, M.B., Harry Angell Lane, John Henry M'Gee, James Stevenson Morton, M.B., B.S., George Percy Shuter, M.B., B.S., and William James Johnstone Stewart, M.B., M.S.

ILKLEY HOSPITAL AND CONVALESCENT HOME.—The annual meeting of this institution, which has now been in existence for sixty-six years, was held at the hospital on April 3rd, Mr. A. Harris presiding. Patients are not ordinarily received all the year round; and the annual report stated that last season the hospital was open for thirty-two weeks, the number of patients being 1018. Dr. Johnstone, the medical officer, reported that of these there were 955 who were either cured or materially benefited. The invested capital approaches £8000, but last year's expenditure exceeded the income by £168, and increased subscriptions are urgently needed.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—A well attended meeting of the South-Western Division was held at the City Asylum, Bristol, on Thursday, April 4th. Dr. Nicolson was in the chair. On the motion of the Chairman, seconded by the Hon. Secretary, a vote of condolence with Mrs. Tuke and family was adopted. It was decided to hold the next meeting on Tuesday, Oct. 15th, at Exeter. Dr. Hubert Bristowe and Dr. Blackford read interesting and valuable papers. Dr. Law Wade's motion on the question of granting gratuities to the widows or orphans of asylum officials who may die after long service or be injured fatally in the discharge of their duties was unanimously agreed to, and the Hon. Secretary was instructed to forward copies of the resolution to the council of the association, also to the medical superintendents of public asylums and hospitals in the division. Owing to the lateness of the hour Dr. MacDonald's paper on the Nursing Staff was postponed till the next meeting. There were several visitors present, and the members and visitors afterwards dined at the Grand Hotel.

MEDICAL MAGISTRATE.—On the recommendation of the Duke of Westminster, Lord Lieutenant of the county, the Lord Chancellor has placed Mr. George Okell, M.R.C.S., Surgeon-Lieutenant-Colonel 3rd V.B. Cheshire Regiment, on the Commission of the Peace for the county of Chester.

MUNIFICENT GIFT.—According to the *Times* Mr. Henry Harben of Hampstead, who has taken great interest in the North-West London Convalescent Homes Fund for Working Men, has decided to erect at his own expense a building at Littlehampton to cost £20,000. The home will contain reading-rooms, &c., and all the latest improvements, and will be lighted throughout by electricity. The work will be put in hand forthwith.

PRESENTATIONS.—Dr. Francis T. Richardson, of Rothbury, Morpeth, was entertained by his friends on the 2nd inst. at a complimentary banquet at the Queen's Head Hotel, on his leaving the district to take up his residence in Edinburgh, and was presented at the same time, as a mark of their respect, with a small souvenir in the shape of a pair of gold-rimmed eye-glasses and a gold-headed cane. The chairman, Mr. W. Forster, of Burradon, in making the presentation on behalf of the subscribers, expressed the general regret felt at Dr. Richardson's departure from amongst them, after half a century's residence. The articles offered for his acceptance were not of great intrinsic value, but he knew they would be prized none the less on that account. On March 30th Mr. J. Kay Tomory, M.B., of Halkirk, was presented by his patients with a purse of sovereigns accompanied by a request that the sum contributed should be devoted to the purchase of a horse and riding outfit. The value of the gift is enhanced by the fact that it consisted largely of small amounts given by the working classes in the district.

THE DANGERS OF ELECTRIC MAINS.—The committee of the members of the Royal Society and the Institution of Electric Engineers appointed to confer with the electrical adviser to the Board of Trade with regard to the circumstances connected with the formation in large quantity of an alkaline deposit in the mains of the St. Pancras electric supply and the presence in this deposit, in some cases, of sodium or potassium, have, it is announced by the *Times*, issued their report. It has already been proved that sparks may be caused by the incrustation itself, and now it appears that the metals just mentioned have been found to exist in the free state in the incrustation, and that they are probably produced from the electrolytic decomposition of alkaline salts, chiefly derived from the soil and conveyed by moisture along the fibres of the wooden bearers towards the negative conductors. It is accordingly recommended that these bearers should be replaced by devices impervious to moisture, and a longer insulating surface between the conductors and the bearers is advised. Steps should also be taken so that the conduits may be inspected throughout their length. Coal gas is, however, regarded as the primary source of danger. The report is signed by Major Cardew, Lord Rayleigh, Professor T. E. Thorpe, Professor Crookes, Mr. R. E. Crompton, Mr. Alexander Siemens, and Mr. Alex. B. W. Kennedy.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Undersized Flat Fish.

THE Government have introduced a Bill making it illegal for any person to "import, export, buy, sell, expose for sale, consign for sale, or have in his possession for sale," a sole or plaice not exceeding eight inches in length, or a turbot or brill not exceeding ten inches in length. The Bill confers on officers of Customs, Board of Trade, fishery committees, and other public bodies ample powers of search and detention.

Reforms in Egypt.

Lord Cromer has made to the Foreign Office another report on the finances, administration, and condition of Egypt and the progress of reforms in that country. In a section devoted to the sanitary department his lordship says that under the intelligent direction of Rogers Pasha much progress has been made. New dispensaries have been opened. The number of patients treated in Government hospitals has increased. An infectious diseases hospital at Cairo has been completed. An English physician is about to be placed in charge of the lunatic asylum. Three new hospitals at Damanhour, Fayoum, and Beni Souef are in course of construction. Slaughter-houses are being built in

several provincial towns. A vaccine institute has been completed. Sixty-six mosques have been placed in a sanitary condition, and 121 cemeteries have been dealt with under the Sanitary Decree passed in January, 1894. Lord Cromer quotes Rogers Pasha to this effect—viz., "It is an undoubted fact that the population is gradually beginning to appreciate the advantages of medical institutions, whether hospitals or dispensaries. Demands are now constantly made for the creation of new dispensaries and hospitals throughout the country, and it is a matter of the deepest regret that the resources of the department should be so limited as to prevent these demands being complied with." In his concluding sentence Lord Cromer expresses the hope that some portion of the general reserve fund may eventually be devoted to sanitary improvements.

HOUSE OF COMMONS.

THURSDAY, APRIL 4TH.

The Tuberculosis Commission.

Mr. Shaw-Lefevre, President of the Local Government Board, replying to a question put by Lord Wolmer, said he must disclaim any personal responsibility for the delay in the issue of the report of the Royal Commission on Tuberculosis, which was largely due to the long illness and death of the chairman, Lord Basing. There had been no delay since the appointment of a new chairman, and he believed that the report was signed on the previous day. A supplementary report by one of the Commissioners was now being printed, and it was expected that this would be signed shortly, and both reports would then be presented.

Factory and Workshop Legislation.

Mr. Asquith, Home Secretary, in replying to a question on this subject by Sir Charles Dilke, said that to extend the interpretation of the term "workshop" so as to include a warehouse not connected with a factory or workshop, where the work carried on was mere packing or bottling, and not in any sense the making or adapting for sale of the article, would be a very great extension of the Factory Acts, and would bring within their operation the establishments of most wholesale grocers, chemists, and drapers. Many of the provisions of the Acts were not really appropriate to the work carried on in these places, and the duty of inspecting them would necessitate a very large increase in the present staff. He must not be understood as holding that warehouses of this kind might not properly be made the subject of statutory regulation; but he thought that if they were to be dealt with, as in the case of shops, there should be special legislation on the subject.

New Legislation for Coal Mines.

Mr. Asquith, on behalf of the Government, introduced a Bill to amend the Coal Mines Regulation Act of 1887. In doing so he explained that the Bill proposes in effect to carry out the recommendations of the Royal Commission with regard to the making of special rules as to explosives and so forth in mines which are dangerous from the presence either of coal damp or coal dust, and makes one or two changes which experience has shown to be necessary with regard to deductions made in the wages of the miners in respect of the presence of foreign materials in coal they turn out.

FRIDAY, APRIL 5TH.

Female Labour in Factories.

Sir Charles Dilke asked the Home Secretary whether, in their recent visits to textile factories for the purpose of making inquiry as to the opinion and wishes of the women workers with regard to overtime, the inspectors had seen the women in the presence of their employers. Mr. Asquith replied that an isolated case appeared to have occurred in which the opinion of the operatives was asked in the presence of the employers, but this was entirely contrary to the usual practice of the factory inspectors, and instructions had been issued which would prevent its recurrence. It was clear that when operatives were questioned in the presence of their employers the inspector might fail entirely to ascertain their real opinions and wishes.

MONDAY, APRIL 8TH.

The Accommodation for Ships' Crews.

Mr. Bryce, President of the Board of Trade, said, in the course of a reply to Mr. Havelock Wilson, that such steps as his department were able to take without fresh legislation with regard to the recommendations of the Royal Commission on Labour affecting Seamen had already been taken, and the question of increasing the minimum crew space allowance would be considered when an opportunity for legislation occurred. All British merchant vessels were required to have for each seaman or apprentice a space of not less than 72 cubic feet, and penalties were provided for contravention of this requirement. Complaints had, however, recently been made to the Board of Trade that in certain vessels carrying Lascar seamen only the space (36 cubic feet for each man) required by the Indian Act had been provided. The owners of these vessels had been informed that the provisions of the Imperial Act must be complied with, and the matter was receiving the careful attention of the Board of Trade surveyors. Representations had also been made to the Secretary of State for India.

Guardians and Infirmary Visitation.

Mr. Macdonald addressed a question to the President of the Local Government Board with reference to a visit recently paid by two guardians at a late hour of the evening to the infirmary of the St. Olave's Union, Southwark, and the complaint made by the medical officer on the subject. Mr. Shaw-Lefevre, in his reply, said his attention had been called to the matter, and he found the facts were substantially as the hon. member had stated them. The Local Government Board had not thought it expedient to fix the hours during which a guardian might visit the workhouse or infirmary; but they had expressed a decided opinion that the case would be a very exceptional one in which it would be proper that a guardian should pay such a visit late at night, and that to justify his doing so there ought to be strong *prima-facie* grounds for believing that special and unusual circumstances rendered the visit necessary. The Board had also stated that a visit late at night ought not to be paid to a sick ward, unless it had been previously ascertained from the medical officer that it would not be detrimental to any of the sick occupants of the ward.

TUESDAY, APRIL 9TH.

Quarantine.

Mr. Shaw-Lefevre, answering a question put by Sir Francis Powell, said that a Bill was in preparation on the subject of quarantine, but as there were many interests concerned he was unable to say when it would be introduced.

The Ventilation of School Buildings.

Sir Francis Powell called the attention of the Vice-President of the Committee of Council on Education to the provisions in the new code for ventilation by enlarged inlets and outlets, in addition to the windows, and asked whether they were not likely to lead to inconvenience and danger to health. Mr. Acland, in reply, said that the size of the ventilators proposed was not unduly large. The teachers, he added, would of course exercise a discretion in opening and shutting windows. It was hoped that the provision would be beneficial and not injurious to the health of the children.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on this subject held another meeting on Tuesday, April 9th, with Sir Walter Foster in the chair.

Mr. James Hamilton, President of the Glasgow Provision Trade Association, examined by the chairman, said that the butters mainly sold in Scotland, apart from home products, came from Denmark and the colonies, and were of good quality; indeed, he thought there was not a large quantity of adulterated butter of any kind sold in Scotland. As to the presence of water in butter, he did not think it would be safe to fix a legal standard, because in its application it would affect injuriously many men honestly engaged in the making of butter, and, moreover, would lead to a general deterioration in the quality of the butter put upon the market. A very large quantity of margarine was sold in Scotland, but very little of it was sold fraudulently. In experience, it was found that the people who strictly conformed to the provisions of the Margarine Act were the people who sold most margarine in Scotland. He had to complain that the Act was not enforced with sufficient stringency, and he recommended that the Government should appoint and pay special inspectors to see to this matter. Margarine he regarded as a good, useful, and suitable article of food, and he would do nothing to interfere with its legitimate sale. He would not have licences for dealers in margarine nor would he prohibit mixtures or the colouring of margarine. Indeed, all he desired was to see the existing law properly enforced.

Mr. Van den Bergh, member of a firm of margarine makers in Holland and Germany, said he was appointed by the London Chamber of Commerce to give evidence on the sale of margarine. Last year his firm turned out 66,000,000 lb. of margarine, all of which was shipped and branded as margarine. In their factories they used from 80,000 to 100,000 lb. of milk per day. He admitted that the colour of margarine as sold resembled very closely that of butter, but it was coloured not to imitate butter, but to make it attractive. If not coloured, margarine would not be appreciated by the public even if sold at a cheap price, and he believed that any interference with the present system of colouring would be disastrous to the margarine trade. He failed to see why margarine should be singled out and coloured pink or blue. He was not in favour of having margarine sold in separate shops. On the whole, he considered that if the present Act were stringently enforced it would be quite sufficient to protect the public. The fines now imposed were quite heavy enough, for upon a third offence no less a fine than £100 could be imposed. He was in favour of travelling inspectors being appointed and of the Customs authorities being compelled to take samples of produce that came into the country unmarked. He should like to see mixtures sold as such, and not, as they were at present, as margarine.

Mr. McCallum, a member of a London firm of butter and margarine importers, who attended at the request of the London Chamber of Commerce, expressed the opinion that the wholesale houses dealt in a perfectly honest fashion with margarine, and the fraud took place after the article left them. He also denied that margarine was coloured in order to make it resemble butter, and he thought that mixtures should be allowed in the interests of the public.

The Committee then adjourned, not to meet again until after the Easter recess.

WESTERN-SUPER-MARE HOSPITAL AND DISPENSARY.—Medical Officer to the Provident Dispensary attached to the Hospital. Salary £60 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BRODIE.—On April 9th, at Chesterfield-street, Mayfair, the wife of Dr. Brodie, of a daughter.
CAMERON.—On April 5th, at 9, Elm-street, Clapham-common, the wife of Albert Cameron, M.B., C.M. Edin., of a son.
CROOK.—On April 4th, at Kepton, Derbyshire, the wife of Herbert G. Crook, M.A., M.B., of a son.
CROOKSHANK.—On April 5th, at Midan Babel Louk, Cairo, the wife of H. B. Crookshank Pacha, F.R.C.S., Director-General of Prisons, of a daughter.
DAVENPORT.—On Feb. 5th, at Chung King, Western China, the wife of C. J. Davenport, F.R.C.S., of the London Missionary Society, of a daughter.
DEVEREUX.—On April 7th, at North House, Tewkesbury, the wife of W. Devereux, M.A., M.B. Cantab., of a daughter.
DIMMOCK.—On April 2nd, at Chatham House, Victoria-avenue, Harrogate, the wife of A. F. Dimmock, M.D., of a son.
RELTON.—On April 6th, at Church-street, Rugby, the wife of Bernard Relton, M.R.C.S., &c., prematurely of a son (stillborn).
REYNOLDS.—On April 8th, at 81, Hornsey Rise, N., the wife of Austin Edward Reynolds, M.R.C.S., L.S.A., of a daughter.
ROLLESTON.—On April 7th, at Upper Wimpole-street, W., the wife of H. D. Rolleston, M.D., F.R.C.P., of a son.
THOMSON.—On April 1st, at Payton-street, Stratford-on-Avon, the wife of Dr. Arthur Thomson, of a daughter.
WARBURTON.—On April 4th, at Langland, Northwood, Rickmansworth, the wife of A. Warburton, M.R.C.S., L.R.C.P., of a son.

MARRIAGE.

ANDERSON STUART-PRIMROSE.—On Sept. 18th, 1894, at Toowoomba, Queensland, Professor Anderson Stuart, University of Sydney, to Dorothy, second daughter of F. A. Primrose, Esq., and granddaughter of the Hon. Bouvier F. Primrose, C.B., Moray-place, Edinburgh, Scotland.

DEATHS.

HARDLEY-WILMOT.—On April 6th, suddenly, Chester Fairley-Wilmot, M.D., B.S. Durh., Senior Assistant Medical Officer at Middlesex County Asylum, near Tooting, in his 28th year.
MEYMOTT.—On April 3rd, at Ludlow, Henry Meymott, M.R.C.S., in his 89th year.
PELLEY.—On April 3rd, at Woodstock House, Lee, Kent, Surgeon-General S. M. Pelley, C.B., late Bombay Army, aged 76.
REEKS.—On April 5th, suddenly, at Southwick, Sussex, John Reeks, M.R.C.S., L.S.A., aged 38.

IN MEMORIAM.

BECKETT.—In affectionate remembrance of Henry Arnold Beckett, a true, faithful, and able friend and servant of THE LANCET for nearly forty years, who died on April 11th, 1894, in his 68th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

UNDER no circumstances do the Proprietors authorise the insertion of loose advertisement circulars and handbills in THE LANCET. Any such announcements are inserted by the newsagents, whom the Proprietors cannot control. At the same time, the Manager will be glad if readers will send him copies of any circulars, with the name and address of the agent through whom they obtain THE LANCET, and the Manager will then endeavour to mitigate the nuisance.

THE LATE MR. J. W. HULKE, F.R.S., P.R.C.S., &c.

MESSRS. BAILLIÈRE, TINDALL, AND COX have sent us a portrait which they have published of the late President of the Royal College of Surgeons of England. The picture has been printed in photogravure by Messrs. Barraud, and is admirable alike as a portrait and as a work of art. Its size, including frame and mount, is 12 in. by 14 in., and the published price is half a guinea. The subscribers intend to follow this portrait by a similar one of the late Sir William Savory.

Mr. John W. Gibson.—The General Medical Council take notice of these matters.

"THE BACTERIOLOGICAL TEST OF THE PURITY OF WATER."—
To the Editors of THE LANCET.

SIRS,—In the last issue of THE LANCET attention is called (p. 835) to a book by Professor Hankin on the process of testing water for microbes for the use of municipal engineers and others. Can you tell me where this pamphlet is to be obtained?—I am, Sirs, yours faithfully,

A. B. C.

* The pamphlet in question is printed and published at the "Star Press" Artillery Bazaar, Agra, price 8 annas.—ED. J.

MEDICAL PRACTICE BY TOUTING.

WE append a number of illustrations of this new system. We are deluged with them. The system must soon come under the notice of the examining authorities, whose disciplinary powers should be used for its repression. We shall revert to a more detailed notice of the evil on an early occasion.

DEGENERATION OF MEDICAL METHODS AT CLAPTON, N.E.

WITHIN a very recent period Clapton and Lower Clapton were neighbourhoods where high professional methods were the rule. We trust the following is only an exception proving the rule:—

"12, Lower Clapton-road (near Clapton-square). Dr. Bremner carries on Practice at the above address. Hours of Consultations: Morning, 9 to 11.30; Evening, 6.30 to 9.30. Fees: Advice with Medicine, from 1s.; Visit with Medicine, 1s. 6d. Midwifery, Vaccination, &c."

We venture to hope that Dr. Bremner has broken the traditions of Clapton without due consideration, and that he will not defend the circulation of such a card as the above.

MEDICAL ADVERTISING AT NOTTING HILL AND THE METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

WE have had forwarded to us a circular which, we are informed, is placed either under the door or in the letter-box of houses in the neighbourhood. The most prominent features of the bill are the names of "Dr. Bluett," 11, Addison-terrace, W. (registered as M.R.C.S. Eng., L.S.A.), and Dr. Pillow, 1, Pembroke-gardens, W. (registered as L.A.H. Dublin, M.D., M.S. R.U. Ireland). The circular is scattered broadcast, and contains not a syllable of restriction as regards wage-limit or social condition. We appeal to Mr. Bluett and Dr. Pillow to say whether they approve of such methods; and we would appeal to some leaders of the profession who like to encourage thrift whether they sanction this indiscriminate appeal.

A CURIOSITY IN MEDICAL ADVERTISING—A TREBLY QUALIFIED MEDICAL MAN "RUN" BY A DRUGGIST!

ANY description would spoil the following:—

"Messrs. Briggs and Co., chemists, 65, Battersea Park-road, beg to intimate that a trebly qualified registered practitioner now resides at above address. Charges: Advice and medicine, 1s.; confinement, 10s. 6d.; home visits, 1s.; vaccination; necessary home visits and medicine for a week, 4s. 6d."

It would be interesting to know more of the personality of the modest gentleman who with three qualifications allows himself to be "covered" by druggists.

MEDICAL ADVERTISING AT THE CAPE.

MR. H. WHEATLEY HART, J.P., Cathcart, Cape Colony, asks our opinion on the following card advertisement from the *Farmers' Chronicle* (Cathcart) of Jan. 11th, 1895. The card is indefensible. The profession in the colonies is as dependent as that in the mother country on the traditions of practice and even more so. A door-plate is the only announcement to be commended. We trust Mr. Nangle will on reflection agree with us:—

"A card.—Dr. E. C. Nangle has commenced practice in Cathcart, and may be consulted at his residence, the cottage lately occupied by Mr. G. J. Taylor, next door to the Standard Bank."

MEDICAL ADVERTISEMENT BY POSTER (20 IN. BY 15 IN.), CAMBERWELL.

THIS is an imposing advertisement. The medical man's name is a conspicuous feature in this bill, and runs as follows:—"Dr. Gallie, 129, Camberwell-road." He is the sole medical officer of the slate club, which "wants" healthy men between seventeen and forty-five, and offers them, besides medical attendance, benefit in sickness, and their families so much at death. Dr. Gallie might be supposed from his description in the Medical Directory to be superior to this kind of thing. He is M.B. Glasg. and C.M., 1882, Member of the British Medical Association, medical officer of Camberwell Provident Dispensary, and surgeon to the P Division of Police. Surely such relations should have restrained Dr. Gallie from consenting to such an unseemly exhibition of his name. If graduates of ancient universities and police surgeons and members of the British Medical Association are to be allowed such licence, what are we to expect in others?

"THE LIQUEFACTION OF HYDROGEN ACCOMPLISHED."

To the Editors of THE LANCET.

SIRS,—A reference to the "Digest," Section 224:4 will refer your readers to an article published in THE LANCET, January 19th, 1878, reporting the liquefaction of oxygen, nitrogen, and hydrogen as one of the greatest discoveries of the year.

I am, Sirs, yours truly,

Boundary-road, N.W., April 6th, 1895. R. NEALE, M.D. Lond.

Justice, a correspondent, points out the frequent appearance of the name and private address of the honorary secretary of the Medical Board, 30, Harcourt-street, Dublin, in the newspaper advertisement of the Meath Hospital and County Dublin Infirmary. The honorary secretary should have his communications addressed to the hospital itself.

THE LATE INSTITUT VIKERAT.

THE following circular was issued by the Institut Viquerat of Geneva. In spite of the merits of the serum of the ass as a cure for phthisis we learn that the institute has been closed, and that M. Perron, the Geneva banker, who is believed to have found the capital necessary for the undertaking, has acquiesced in the cessation of the manufacture of the fluid.

"HEALING OF CONSUMPTION AND VARIOUS CASES OF TUBERCULOSIS."

"Discoveries of Dr. Viquerat.

"Every one knows that consumption has two different phases; in the first the tuberculosis bacillus is alone to his destroying work; in the second two others microbes are coming on with the first and hasten the course of sickness, which is then complicated with suppuration. The prepared serum of the ass discovered by Dr. Viquerat cures absolutely tuberculosis, that is no more to argue with the numerous recoveries made. But prepared ass serum alone cannot overcome consumption in her last phasis, when suppuration and hectic fever have come to complicate the trouble. It was then of importance for completing the deed, to add, to ass serum speciale serums appropriated for suppuration. Dr. Viquerat has searched a long time, and, one of those serums form his second great discovery. The goat furnish this serum. In November 1894 the Institute had announced that those serums would be ready in March 1895; but the preparation has been made a little sooner. The action of those serums takes soon away the hectic fever and suppuration. It ensue (this dreadful complication no more existing) that the physician has only the single tuberculosis to heal. And, it is now known that the prepared serum of asses; heal perfectly tuberculosis in some months. Then, with those discoveries, all no-cachectic consumptives who have sufficiently healthy lungs to subsist could revive to health, but, one must understand, that science cannot do more: make again organs that have disappeared. To heal every sickness, organism shall offer sufficiently power to help the struggle against the trouble. All persons troubled with weak chest, all kind of tuberculosis, and the consumptives who wishes to place themselves under the medical treatment of the Institute, will be able to do so by coming to Geneva for the length of the cure. They will be able to settle in the numerous hotels or boardinghouses in the town, and can be attended at their lodgings, when momentarily unable to come to the Institute. The price of the medical treatment is 350 f. monthly. The Institute having momentarily a relatively little quantity of anti-suppurative serum, the patients affected with suppuration and hectic fever, shall register themselves as soon as possible. They will be treated in the range of inscription. Please send with the registry a cheque or postal order of 25 frs, it will be worth on the treatment price. The registry is unnecessary for the patients who have single tuberculosis, the Institute having enough anti-tuberculous serum for all demands. Patients are advised that Dr. Viquerat occupies itself exclusively of the laboratory works and that the treatment in the Institute is placed under the direction of the clinic chief physician M. Dr. Jacot. All what concerns the Viquerat's Institute shall be addressed to Mr. Ch Perron.

"Ch. PERRON,

"Director of Viquerat's Institute.

"Côte-Drize, Geneva, 25 January 1895."

MR. II.—We never depart from our rules in these matters. We can neither recommend individual practitioners nor suggest treatment.

A WARNING.

To the Editors of THE LANCET.

SIRS,—A tall fair woman, stating she is a Russian and destitute, is calling round the neighbourhood of Harley-street complaining that a medical man of whom she has begged for some time will not give her any more money. He has helped her on several occasions, but on having a report from the Charity Organisation Society declined further assistance, and has placed the matter into the hands of his solicitor, Mr. Robert Todd, of 1, York-buildings, Adelphi, who would like to hear from anyone to whom she may apply. I write this to put the members of the profession on their guard. I am, Sirs, yours truly,

April 9th, 1895.

M.D.

WANTED, A HOME.

To the Editors of THE LANCET.

SIRS,—Can you or any of your numerous readers inform me of a home where the sons of a deceased medical man, who has left no provision for them, can be taken in free, or with very small premium?

I am, Sirs, yours faithfully,

April 10th, 1895.

J. N.

J. C. B.—There may be some business or legal reason for the advertisement sent us for which the parties to it are not responsible. We do not feel called on to comment upon it.

L.S.A.—Our correspondent is at liberty to describe himself on his door-plate as "Physician and Surgeon," whether he does so or not being a matter of taste. His neighbour is clearly wrong in prefixing "Dr." to his name.

THE CASE OF MR. C. BRYAN TOWNSEND.

The following donations have been received in addition to those already announced and are hereby thankfully acknowledged:—

Dr. G. Fielding Blandford	£1	1	0	Dr. George Macdonald	£3	3	0
A "Sympathiser," per Dr. V. Dickenson (London)	3	3	0	Dr. James Black (London)	0	10	0
Dr. E. W. Emtage (Holeworth)	0	5	0	Dr. F. G. Burghard	1	1	0
Dr. A. Watson (London)	0	5	0	Dr. E. Nettleship	3	3	0
Dr. T. Morton (Kilburn)	1	1	0	Dr. W. H. Fenton	2	2	0
Dr. C. W. Chapman (London)	1	1	0	Dr. Wharton P. Hood	5	0	0
P. G. ...	0	10	0	Dr. Cheadle	2	2	0
E. E. ...	0	10	6	Dr. G. Anderson	2	2	0
Dr. W. T. O'Grady (Swinton)	1	1	0	Dr. William Hunter	1	1	0
Dr. R. Paramore (London)	0	10	6	Dr. Woodhouse Braine	2	2	0
Sir Henry Thompson	3	3	0	Dr. R. B. Townsend (Oxford)	1	0	0
Dr. C. A. Ballance	2	2	0	Dr. W. P. Herringham	1	1	0
Dr. Cullingworth	1	1	0	(London)	3	3	0
Dr. E. Clifford Beale	1	1	0	Dr. Pearce Gould	0	10	0
Dr. Ed. Liveing (London)	1	1	0	P. G. ...	0	10	0

Further donations are earnestly invited by the Rev. H. Townshend, 41, King Henry's-road, South Hampstead, N.W.

Inquirer.—It is now necessary for a practitioner who desires to practise in France and possesses English degrees or licences to pass at least the two final examinations required for the French M.D. degree. For this a knowledge of French is indispensable. The old diploma of *Officier de Santé*, which at one time was commonly taken by English practitioners, is now abolished.

Cedric has omitted to supply us with his name and address.

RUPTURE OF THE QUADRICEPS EXTENSOR TENDON.

To the Editors of THE LANCET.

SIRS,—I was called at 11 P.M. on the 22nd ult. to a postman who was said to have injured his knee. On his way home after a long day's work he stumbled when about a quarter of a mile from his house, and in endeavouring to check himself from falling backwards he heard a distinct snap and felt a sharp pain above his right knee-joint. With great difficulty he hobbled home. On examination I found the patella intact, but abnormally movable. The upper border of the bone was sharply defined, and above it was a distinct gap, in which subcutaneous ecchymosis was evident. In this region there was dull aching increased by pressure. There was total inability to extend the right leg. Mr. Kirkpatrick, who saw the case next day, agreed in my diagnosis of rupture of the quadriceps extensor. As this accident appears to be rare, we thought it might interest the readers of THE LANCET. The patient thinks that the tendon was weakened by his former occupation of shoemaking, in which there is constant hammering over the region in question. It would be interesting to hear of recent similar cases in hospital practice and what treatment has been found successful. The patient in question is sixty-two years of age, healthy and active.

I am, Sirs, yours faithfully,

Woodbridge, April 1st, 1895. EDWARD C. B. ISOTSON, L.S.A. Lond.

* When a violent contraction is made by the quadriceps extensor muscle of the thigh in order to avert a fall any one of four lesions may occur. By far the commonest is a transverse fracture of the patella, and this is especially likely to happen if the knee is flexed. Very rarely it happens that the ligamentum patellæ or the tendon of the quadriceps extensor gives way, and these two lesions seem to occur with almost equal frequency. But rarer still is rupture of the substance of the muscle itself; for Delon was able to collect thirty-six cases of rupture of the tendon of the quadriceps, but only six cases of rupture of the muscle. The above case is an interesting example of rupture of the quadriceps tendon. The treatment of this condition merely by rest and splints gives very fair results and useful limbs; but with due antiseptic precautions a more energetic treatment may sometimes be adopted, for Chaput in 1889 sutured the ruptured tendon in one case with a perfectly satisfactory result (*Société de Chirurgie*, Paris, December, 1889).—ED. L.

A QUESTION OF FEE.

To the Editors of THE LANCET.

SIRS,—What could be considered a reasonable fee to charge the Rural District Council for each visit to the isolation tents, which are a mile and a half from my residence? I am, Sirs, yours truly,

INQUIRER.

* Without further particulars it is a little difficult to answer our correspondent's question as precisely as we could wish. Assuming, however, as we do, that the arrangement proposed is to be a special and temporary one, and that our correspondent is to advise as to the general control of the camp, we think a fee of one guinea per day, to include, if necessary, more than one visit, would be a fair remuneration.—ED. L.

HILL'S PATENT EGG-CUP.

AN ingenious novelty in culinary appliances has been forwarded to us by the Premier Egg-Cup Co., 22, Imperial-buildings, Ludgate-circus, E.C. It resembles a deep, rather narrow porcelain tea-cup without a handle, having a German silver lid, which screws on. The raw egg is cracked and the contents turned neatly into this cup; then the lid is securely fixed, and the whole boiled just as if it were an egg in the shell, but for a minute or two longer than the usual time. The cup can be lifted out of the water with wire tongs, and after being wiped is sent to table unopened. The lid being then unscrewed, the contents are eaten just as out of the natural shell. A practical trial has fully justified the description given by the vendors, an egg cooked in this way being equal to an ordinary boiled egg, and free from the wateriness and loose texture of a poached egg. An obvious advantage is that the cook can make sure of the soundness of an egg before sending it to table, and two or more small eggs may be conveniently combined in one of the larger sizes of cup.

C. B. M. S.—We see nothing to object to in the arrangement suggested. It is certainly true that there is much need of instruction in the elements of good home nursing; and it cannot be given more carefully or with more precaution against abuse than by a medical man.

PRACTICE IN NEW ENGLAND.

To the Editors of THE LANCET.

SIRS,—Can any of your readers say what chances a Scotch graduate would have for medical practice in the New England States of North America if he were to go out there? Information through your columns will be gratefully received.—I am, Sirs, yours faithfully, April 9th, 1895. X. Y. Z.

* In our opinion a Scotch graduate would have no obvious claim on the attention of the public in these particular States. America is well supplied with universities, ranging from the very good to the very bad, all of which give the title of M.D. to their students, while the New England States are by geography likely to attract the graduates of the Canadian Universities also.—ED. L.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY.—ROYAL METEOROLOGICAL SOCIETY (25, Gt. George-st., Westminster).—7.30 P.M. Mr. F. Campbell Bayard and Mr. Williams Marriott: The Frost of January and February, 1895, over the British Isles.—Mr. Birt Acres: Some Hints on Photographing Clouds.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover-sq., W.).—3 P.M. Mr. A. D. Michael: On the Form and Proportion of the Brain in the Oribatidae and in some other Acarina.

NORTH-WEST LONDON CLINICAL SOCIETY.—8.30 P.M. Clinical Evening.

THURSDAY.—HARVEIAN SOCIETY.—8.30 P.M. Clinical Cases. Dr. Alexander Morrison: On Syncopal Brady Cardia.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France J. ASTIER, 2, Rue Traversière, Asnières, Paris.

An Address

ON

THE MEDICAL PROFESSION: ITS PLACE AND PROGRESS.

Delivered before the North London Medical and Chirurgical Society on April 11th, 1895.

By JAMES GREY GLOVER, M.D. EDIN., &C.,

PRESIDENT OF THE NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY;
VICE-PRESIDENT OF THE CLINICAL SOCIETY; DIRECT REPRESENTATIVE OF THE PROFESSION IN THE GENERAL MEDICAL COUNCIL, &C.

GENTLEMEN,—You will not expect from me an address comparable to those with which we have been favoured many times in the short history of this society—not least in the course of the session now drawing to a close—from men of eminence in the consulting ranks of the profession or in those regions of pathological and biological research whose work makes the last part of the nineteenth century memorable in the history of medicine and of Queen Victoria. Mine will be the humbler function of reviewing from the standpoint of a general practitioner the ground we occupy as a profession; of noting the principal changes I have seen in practice and estimating their importance, and possibly of forecasting the lines of probable development and progress of medicine. There are some who take a gloomy view of the future of the general practitioner, who think that between the consultant and the specialist, backed by the hospital system, not free, it is admitted, from great abuse, he is likely to be extinguished, or at the very best relegated into a position entirely secondary and subordinate, similar to that of the old apothecary. It is curious to notice, in contrast to this, an opposite set of fears which, it is said, occur occasionally to the consultant class. I have heard it said that consulting surgeons are concerned at the growth of surgical aptitude among their pupils, and at the boldness with which they undertake feats of surgery, the only consolation being the occasional scrape in which these audacious young gentlemen land themselves, for escape from which they have to appeal to their superiors. It is always dangerous, however, to prophesy the future of any great branch of medical work. I lately heard on the best authority a very striking illustration of this, and as I have the kind permission of those principally concerned to mention it I gladly use it. It has reference to a period seventy years back, and to a then young physician who afterwards became distinguished—I mean Dr., afterwards Sir George, Burrows. My informant is Mr. Willett, son-in-law of Sir George Burrows. When it was determined that Dr. George Burrows, having graduated in Cambridge, should commence practice in London as a physician, Sir William Lawrence called on Dr. Burrows's father, Dr. Mann Burrows, to induce him to dissuade his son from starting as a physician in London—i.e., as a hospital and consulting physician—because in his (Sir William Lawrence's) opinion physicians would soon cease to exist through there being no demand for them in London, adding that if the son were determined to be a physician he might succeed in Manchester or some other large provincial town or centre. Those who remember Sir Wm. Lawrence will best know how striking this illustration is. He was one of the acutest of men and the most far-seeing. Yet nothing can be further from the fact than his forecast. Sir George Burrows lived to be one of the most successful and eminent physicians of London; the number of consultant physicians has been largely multiplied, and so has their success, and if there has been any difference the movement has certainly been from the provinces to the metropolis rather than from the metropolis to the provinces. Such extreme views as I have quoted correct each other, and we may conclude that, the great social conditions of life remaining the same, and the great wants of human nature in a medical respect being subject to but little variation, there is likely to be the same steady demand for medical service and its different forms and grades as exists now, and that it will depend very much on the profession itself how far it will be consulted and on what terms. Certainly, there seems no reason at present, despite the growth of specialism, to

No. 3738

think that the general practitioner will cease to be much needed in the economy of things. The facilities for special study in medical education are being multiplied in every medical school of any consequence, and it will be the fault of the medical student if on finding himself a practitioner he has not a knowledge of the elements of all the specialisms, which it has never been so easy to gain before. Before leaving this subject I wish to say a word on the great importance in the curriculum of medical education of a certain amount of pupillage in general practice. Some of us have been partially successful in the General Medical Council in getting this truth recognised: I am pleased to add, with the concurrence of such leaders as Sir Wm. Gull, Dr. Wilks, Sir James Paget, and others. Just as men need to have lessons in hospital practice, so they need lessons in general practice. The practice is quite different. The very cases are different, and their management and even treatment are different. But especially the cases are different. The great bulk of the cases that constitute general practice are conspicuous by their absence in the wards of a hospital and would be considered uninteresting, so that it is possible for a distinguished student, and even one who may have been a resident physician and surgeon, on commencing general practice, to find himself in considerable difficulties alike of diagnosis and of treatment. One great enemy of the general practitioner, and especially of the young general practitioner, is not so much the specialist as the generalist—that arch-generalist, the prescribing chemist—with his ready platitudes of diagnosis and his equally ready remedies for every complaint, from that of the teething infant to that of the ailing woman or man on whose health the happiness of a whole family depends. I sincerely believe that one of the best ways of meeting this unfair competition is the education of the medical student in common diseases—in the perception of their importance and in a readiness to recognise and relieve them. The tendency is rather to make light of them. This tendency should be denounced. A child with a distended tooth sac is not to be relegated to chemists. It is on the verge of convulsions or diarrhoea or bronchitis, and is not to be put off with a powder or a diarrhoea mixture. The profession must keep in touch with the common diseases of the common people or it will hand over whole branches of practice to the druggist, and we shall hear more of the hardness and the decline of general practice. I magnify the office of the general practitioner in his responsibility for the treatment of ordinary cases, believing with Sydenham, who said:—"Nevertheless I have always thought it a greater happiness to discover a certain method of curing even the slightest disease than to accumulate even the largest fortune, and whoever compasses the former I esteem not only happier but better and wiser too. With respect to practice I declare that I have faithfully set down all particulars also that I have contributed to the utmost of my abilities that the cure of diseases might, if possible, be prosecuted with greater certainty after my decease, being of opinion that any accession to this kind of knowledge, though it should teach nothing more pompous than the cure of the toothache or corns, is of much greater value than all the vain parade of refinements in theory and a knowledge of trifles, which are perhaps of as little service to a physician in removing diseases as skill in music is to an architect in building." But, though I think strongly that the success of the profession is largely dependent on its familiarity with the common diseases of the people and on sympathetic readiness in the use of means for their relief—in other words on the efficiency, sympathy, and accessibility of the general practitioner—I am under no delusions as to the abolition of the higher branches of professional work. No man recognises more cheerfully than I do the increasing earnestness and authority of consultants and their value in the economy of things. The most experienced general practitioner best knows the comfort and the satisfaction of calling to his aid men, whether young or old, whose studies, or genius, or experience, or practice in the various parts of our vast empire, have added to our knowledge of disease, or whose skill in the treatment of difficult cases has been recognised alike by the public and the profession. It would be strange indeed, and as discreditable as strange, if in a wealthy nation and with a social life ever becoming more complicated and exacting, the necessities for such authoritative members of the profession did not multiply and if their rewards did not increase. I am tempted here to quote Mr. Gladstone, speaking in 1890 at Guy's Hospital of the great start taken by the profession in the last century in the

time of Freind and Mead: "That profession has been steadily rising in power, in influence, and in general respect from that date to this, and it is my belief it will continue to rise. The growth of civilisation, as we call it in a large and comprehensive, but in a very loose and indefinite phrase, carries with it the production of many new forms of infirmities and disease, and men's wants in the medical sphere are the opportunities of the medical man." Lord Salisbury has spoken, too, within a year or two in very important terms of the profession and its work. It was on the same occasion at Guy's Hospital that Mr. Gladstone made two remarks on the financial aspects of our calling that deserve our attention. He referred with satisfaction to the great professional fortunes that were accruing to medicine, and secondly he complimented us on our independence, and said there was no great profession which had dipped its hand so modestly and moderately into the public purse. So far so good, but Mr. Gladstone's friendly remarks need this reply: The great medical fortunes might be counted on one's fingers or even one's thumbs, and have not kept pace with the growth of national wealth. If a statement could be got of the average net income of the profession it would surprise our financiers who tax us so complacently. Secondly, I shall have to show in a few minutes that if the profession has kept its hands out of the public purse more than other professions, it has done an enormous amount of unpaid or ill-paid work for the poor, and has been allowed to do it in a way scarcely creditable to the State or to the public.

So much for the ground we occupy as a profession in its two main divisions of the general and the consulting practitioners. There need be no jealousy between them, and there should be no rivalry. They should help each other and sympathise with each other, and respect each other's functions. Neither of them singly is equal to the whole care and cure of disease. They should coöperate; and I know no place for bringing them to a better understanding of each other and of disease than such societies as that of which we are members. Here they can each make their own special contribution to the illustration of disease and stimulate one another to a deeper study of it; and if there is any root of bitterness or element of friction amongst us, this is the kind of place for its full and friendly discussion. I know that our larger societies have not been so used. Perhaps, rightly so; but I am disposed to think that this exclusion of all medical ethics and politics from the societies has been carried a little too far. No one would regret more than I should the distraction of our scientific societies by frivolous or petty questions of medical or ethical politics; but there are some such questions which are neither petty nor frivolous, which involve the very reputation and efficiency of the profession, and on these, I think, our medical societies, because they are in the main scientific societies, might occasionally confer with advantage to the harmony and solidarity of the profession. For want of such conferences between the consulting and general branches of the profession one is pained occasionally to see indications of a want of sympathy between these branches, as if their interests were different.

Any review of the place and progress of the profession since I have known it would be very incomplete which did not take note of the enormous development of medical work done in the way of preventing disease. The State under the lead of such men as Mr. Chadwick and Sir John Simon has come to see that disease is an immense factor in the retardation of the progress of society, and that it is largely preventable. In a time when the notion of personal liberty in all directions grows almost excessively, there is one direction in which it is being discouraged and denied—that is, the liberty to have avoidable disease, to live in an insanitary house, or to generate smoke or other nuisance that may be injurious either to one's self or to one's neighbours. The subject of certain avoidable or communicable diseases is no longer a free agent or master of his own house. His illness is a matter of public importance and must be communicated to the public authorities. The chief agent in this communication is the medical practitioner. In a large proportion of the cases the patient is taken or voluntarily goes to public institutions to be treated gratuitously by medical officers appointed by the State or by a Board created by law. In my younger days the only public medical officers were the parish doctor and the medical officer of the workhouse. Now, one of the most important factors in a parish is the Medical Officer of Health, who, through his "authority," has enormous powers over property and over the liberty of individuals. A question was put in Parliament the other

night by the members for Islington which implied not only the power but the duty of the State in such institutions to practically incarcerate a patient with scarlet fever if need be for the best part of 100 days. Such duties and such relations of the medical profession immensely increase its importance and its responsibility. It needs in its facts to be unimpeachable and in its judgment to be impartial. While other professions are rather losing touch with the State, are threatened, in the language of the day, with "disestablishment," ours seems to be undergoing a sort of opposite process. So bent is the State on the prevention of disease—so properly bent—that the very material of our work is lessened by its operations. The profession is supposed to be the great mainstay of the Vaccination Laws, and by some foolish people to be so on selfish grounds. "Of course we approve the Vaccination Laws because we like the vaccination fees"; so runs the argument, forgetful that the vaccination fees are very small, and that a good long illness of six weeks would be much more profitable to the profession. It is certain that either for the prevention of disease or its cure the State will not on this side of the millennium be independent of the medical profession. It is sad to think that so far it is poorly paid; that its most illustrious members are but slightly regarded by the State and conspicuous by their absence in her great councils. But this will not always be so. We are, after all, the most indispensable of the professions, and if we were only true to each other we could compel very different recognition both from the public and from the State. The medical officers of the Services have often set their civil brethren an example in this respect, of a little more dignity and unanimity of demand, and the sooner we follow the example the better. The profession has long accounts to settle with the public and with the State. In its way—a really shabby way—the State has made medical provision for actual paupers; but *pauperism* is going out of fashion. We no longer speak of pauperism, but of poverty. This difference is accentuated in the case of all medical relief, so that the State has called on its medical officers to give relief to citizens to whom it would give no other relief, and who are to lose no right of citizenship by accepting it, but who would lose such right by accepting other forms of relief. What is the meaning of this exceptional position of medicine unless it be that it is indispensable. This is a cheap way on the part of the State of using its medical officers for those who are not-veritable paupers. The public in its philanthropic capacity does very much the same thing. It allows the medical profession to do its medical charity. There is a huge population so poor or so improvident as to have no regular understanding with a medical man, but who rush to him in emergencies and who ring his bell urgently at midnight when all other good citizens are fast asleep, and expect to be attended to on grounds of humanity. I agree that there is something so pitiful in the emergencies of disease that this is almost inevitable; but I am amazed that the public or the State has so long left all this work to be done by anybody or anyhow without thought of its own responsibility to the profession which does it. I will give you an example of what I mean, not inapt at this time, when the question of midwives is before the public and the profession. I was asked to see a poor but respectable woman with seven children, lately confined. She had been delivered by a midwife, who had to call a medical man out of his bed to remove an adherent placenta, which he did efficiently. The woman was much blanched, besides being the subject of chronic phthisis. I found, only by categorical inquiry, that while the midwife had her 10s. 6d. fee, the medical man had had no fee for his obstetric services, and apparently expected none. Has society, has the State, no duties towards the medical man who does the good Samaritan in this way? Is the public for ever to have all this medical charity done vicariously? We shall see. Now that the decent poor are to be helped without taint of pauperism the scandal of medical charity at the expense of the medical profession alone must be removed.

I have left myself so little time that I must say but a few words on the principal changes which I have seen in practice and their significance, without any severity of arrangement or any pretension to exhaust the subject. I think the following headings would include the chief facts: 1. The introduction of *anæsthesia*. 2. The disappearance of the antiphlogistic treatment of disease and the introduction of one which aims at supporting the powers of nature, by which it is recognised that disease is chiefly combated. 3. The doctrine of *sepsis* and the application of antiseptics to

surgery, medicine, and midwifery. 4. Increased care in the study of the *causes* of disease and the discovery in many diseases of the bacteriological nature of their cause. 5. Increased care and time in the *diagnosis* of cases, especially in the determination of the element of pyrexia by the use of the clinical thermometer, in the use of bacteriology, &c. 6. In Midwifery the shortening of the second stage of labour by the more common and early use of the forceps and the improved treatment of placenta prævia, and, above all, the protection of the lying-in woman from all contamination with specific contagia by extreme cleanliness, their careful exclusion, and the use of antiseptics. 7. The recognition of the relation of great groups of disease to an underlying and often inherited diathesis or constitution. 8. The enlargement of our conception of therapeutics as embracing much besides mere drugs; a more open mind for new remedies, with unabated respect for old ones; more or less successful attempts at theories of the mode of action of drugs. Each one of these headings would be worth a separate address by a capable speaker. I am only giving you the impressions made on a general practitioner who has had neither the time nor the ability to go deeply into the questions which they cover. Looked at cursorily and in their combination they show a broadening and strengthening of the very basis of medical science and an enormous addition to the beneficial and curative powers of the profession. The first change I have noticed is Anæsthesia. This discovery alone would have conferred lustre on the history of medicine in this century, but it is too obvious and too big a fact for more than mere mention here. I notice next the Disappearance of the Antiphlogistic System. There can be no doubt that this is a great improvement. Though it is doubtless true that there are cases which would be mechanically relieved by a moderate and careful phlebotomy, it must still be admitted that the old practice, which added the complication of anemia to every acute disease and not a few chronic ones, was one of those errors which can only be regarded as the result of the undue reign of mere authority and imitation. As to the theory of change of type of disease by which this change of practice was sought to be covered and explained, I have a very limited belief in it. The ordinary acute pneumonia, which, occurring in a single member of a family and going through the typical stages made familiar to us by Bennett, Fox, and other writers, is very much the same thing as I used to see as a youth. I am aware that this ordinary pneumonia is considered by many physicians as "an infectious disease" depending on a micro-organism invariably found in the diseased lung. But surely there is another pneumonia abroad which, if not new or newly recognised, has been recognised with fresh vividness, with its qualities of asthenia and of infectiousness, which place it altogether in a separate category. I would especially refer in this connexion to the report of our distinguished neighbour, Dr. Ballard, on the epidemic of pneumonia in Middlesbrough in 1888, which affected 1633 persons out of a population of 97,608 and caused 369 deaths, or 16·7 per cent., which he called a specific fever, like which (specific fevers) it possessed the quality of communicability from the sick to the healthy, either immediately through proximity, or mediately through food or otherwise. "It has seemingly," he adds, "its own specific *contagium vivum*, 'the bacillus pneumoniæ' of Klein, which he has captured, isolated, and studied"; with which, by inoculation or in the way of food, he produced a similar fatal pneumonia in mice and guinea-pigs. I have myself known three deaths from pneumonia of adults within as many weeks in a country house with every comfort and luxury in it. I make the less excuse for allusion to this epidemic as it has had too much interest for us in recent influenzal seasons, and because its investigation by Dr. Ballard on behalf of the Local Government Board is one of the best illustrations of the thorough and deep investigation of the nature of disease which contributes the best basis for means for its prevention and treatment. I will not detain you in any laboured vindication of the value of the sustaining and restorative treatment of disease as compared with the antiphlogistic; but I will only add my belief that this theory is occasionally pushed too far, especially in the old, and that both stimulants and food are stuffed down the patient's throat in a mechanical sort of way, to his embarrassment rather than his advantage, as if he were a cask for the passive reception of such things, and not an organism with digestion and every other function in abeyance. We have to remember that food and nourishment are only good in as far as they can be appropriated and assimilated—that all beyond this creates

discomfort and difficulty for the loaded and disordered organs. The Antiseptic system needs no laudation from me who have no claim even to praise that of one who early discerned its significance, and has looked with ever-increasing admiration on its success. It has revolutionised surgery, and seems to me the greatest improvement since the discovery of the ligature by Ambrose Paré. It is impossible for those who did not live in pre-antiseptic days to know the difference in surgery. The finest surgery was marred by the frequent appearance of septicæmia in a few days from the operation, and when this did not happen the wound or the compound fracture was often the seat of a suppurating that yielded pints of matter, and not infrequently a lively brood of living and by no means microscopical animals—which stank and poisoned other patients in turn. Three words will express for all time the chief achievement of Sir Joseph Lister: "He abolished pus." And if the achievement seems at first sight somewhat less than that of Paré, as the loss of pus is less terrible than the loss of blood, yet in other respects the merit is greater, as the intellectual process by which the system was established was more subtle and profound. In its application to midwifery and gynecology the Antiseptic principle has been unspeakably beneficial, and has saved and is destined to save thousands of lives. It has especially rescued lying-in hospitals from a discredit which threatened their extinction. It is only fair to say that Semmelweis in 1847 in a way anticipated the antiseptic system in the matter of midwifery, but only in a way. Be this as it may, we owe to the system introduced so ploddingly, through evil report and good report, by Sir Joseph Lister an extension of operative surgery undreamt of before his day and a success of it which is simply brilliant, and which brings it into serious competition with medicine in many fields hitherto regarded as the exclusive domain of the physician. I must here emphasise the two great achievements of recent midwifery proper which, after the antiseptic system, strike me as its greatest improvements. The first is the freer and earlier use of the forceps, shortening the duration of the second stage of labour, which, as Sir James Simpson showed, had much to do with the complications and disasters of the after puerperal condition. True we have heard much more of late years of accidents to the perineum. But these have been carefully and antiseptically dealt with. I may mention one little precaution of my own which I have found effective for the prevention of such accidents, which is, of course, better than the most scientific suturing—viz., when you use forceps to procure the aid, where possible, of a brother practitioner to take charge of the perineum. This is a very simple precaution and in out-of-the-way places perhaps an impracticable one. But I can commend it from experience. The next great achievement of midwifery is the improved treatment of Placenta Prævia, by which the patient, after the nature of the case is clear, is practically not left till delivery is accomplished. It is gratifying to think that this improvement is most honourably associated with the names of British obstetricians, notably Dr. Barnes, Dr. Braxton Hicks, and Dr. Murphy of Sunderland. The last physician has published a record of sixty-three cases with only two deaths, and in one of these the patient was moribund when first seen. My fourth point is the improved care and means in Diagnosis especially—e.g., in the determination of the question of pyrexia, or otherwise, by the use of the clinical thermometer, in the application of bacteriology, and, I would add, the closer and more practical study of physiology in its bearing on the problems of health and disease. I need not detain you with illustrations of this proposition. I have only met with one member of the profession who did not use a clinical thermometer, though I have known many, including myself, who use it too infrequently. I am persuaded that no instrument does so much to put us on our guard and to save us from grave neglect of diagnosis; for after all many of our errors come from carelessness and off-handedness. Having once ascertained the existence of pyrexia, we are on the safe road to find out its significance in the particular case. Of course, the mere absence of pyrexia is no guide in a large proportion of our graver cases. It would be presumptuous in me to enlarge on the part played and to be played by Bacteriology in diagnosis. We seem to be at the mere threshold of a new region of light. But already which of us is not indebted to it for aid? I am sorry that a resolution in the General Medical Council, moved by Dr. Philipson and seconded by myself, for securing more attention to this subject in medical education was lost. Of course, this was from no inadequate sense of the subject

In the minds of the members of the Council, but from their assuming that it will be taught. Meantime most busy practitioners will be thankful to be members of the Clinical Research Association, which quickly determines for us the bacteriological or other facts of any given secretion. It is no slight proof of the increased carefulness of practitioners, that in six months this association has examined 2000 specimens sent from various parts of the country. It is only fair to medical teachers to say that physiology and all other fundamental subjects are now taught in a practical way with a view to their bearing on the great problems of health and disease.

I have not left myself time to speak of the changes to be noted in larger conceptions of therapeutics and more accurate views as to the action of medicines. Though mere drugs are no longer regarded as the be-all and end-all of the practitioner, they were never more indispensable than now. The discovery, for example, of Laveran's bodies—the essential cause of ague and so admirably illustrated lately for this society and for the profession by Dr. Patrick Manson—has not superseded the use of quinine. Rather has it afforded fresh demonstration of its power, for it is found to destroy these very bodies and cause their disappearance from the blood. How real and persistent is the reputation of our old remedies—quinine, mercury, opium, alkalies, and iodide of potassium; but how much our store of remedies has been enriched by the addition of the bromides, salicin and its compounds, atipyrin, phenacetine, pilocarpine, iodoform, nitrite of amyl, nitro-glycerine, boric acid, &c. We are deluged, indeed, with new medicines, and they come to us in quantities which are embarrassing. Still, truth compels us to admit that they come in pharmaceutical forms which are a great improvement on old ones. The admirable preparations of active drugs for hypodermic use enable one to carry a medicine-chest in the pocket of our coat, and to minister to urgent symptoms when medicine in ordinary forms administered by the mouth would be rejected. The wonders wrought by thyroid feeding—of which a happy instance was recorded at our last meeting by Mr. King—are a revelation. It is perhaps premature to speak dogmatically of the treatment of diphtheria by antitoxin; but it is significant to notice the lower range of mortality from diphtheria in the metropolis since its introduction, and we have good reason to hope that a new realm of therapeutics has been sighted. Very remarkable, too, are the results of alimentation and massage in properly selected cases, and of the action of natural waters to be found in our own and other countries. The direct introduction of antiseptics into the trachea and bronchi in cases of phthisis and other forms of chest disease has been lately shown by Mr. Colin Campbell and others to be both practicable and beneficial. Speaking generally we have outlived the idea that disease is to be treated by drugs alone. But we are no nearer the time when they can be dispensed with or administered in impalpable quantities without injustice to our patients and unfaithfulness to our art. The forecast from such achievements as I have summarised I shall leave to my audience. The subject is tempting, but your time is gone, and I must bring my address to a close. I cannot do so without a word of gratitude to my colleagues generally and the secretaries, who have so well piloted the society through a session of some anxiety and difficulty, and have provided us with admirable material for professional instruction and reflection. I can imagine nothing better for a man in general practice than to be a member of such a society as this, if not of more than one. By contact with fellow practitioners and by seeing constantly a number of interesting cases he keeps his knowledge of disease and its remedies fresh. Differences of opinion are adjusted, and where that cannot be men still learn to respect each other and each other's views. Let us do what we can to promote these great ends of all medical societies and in every other way to advance the harmony, the reputation, and the usefulness of the profession of which we all feel it an honour to be members.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. R. Langerhans, *privat docent* in Pathological Anatomy, has been granted the title of Professor.—*Gießen*: Dr. Sommer of Würzburg has been appointed Extraordinary Professor of Mental Diseases.—*Turkief (Dorpat)*: Dr. Babnoff of Moscow has been appointed Professor of Hygiene; Dr. Ignatovski of Kiev has been appointed to the Professorship of Forensic Medicine.—*Strasbourg*: Dr. Cahn has been promoted to an Extraordinary Professorship of Medicine.

The Lancelian Lectures

ON

THE DIAGNOSIS, PROGNOSIS, AND PROPHYLAXIS OF INSANITY.

Delivered before the Royal College of Physicians of London on March 28th and April 2nd and 4th, 1895.

By G. FIELDING BLANDFORD, M.A.,
M.D. OXON., F.R.C.P. LOND.,

LECTURER ON PSYCHOLOGICAL MEDICINE, ST. GEORGE'S HOSPITAL.

LECTURE III.¹

Delivered on April 4th.

THE PROPHYLAXIS OF INSANITY.

MR. PRESIDENT AND GENTLEMEN,—I come now to the third portion of my subject—the prevention of insanity. On Jan. 1st, 1894, there were registered as of unsound mind, according to the Report of the Commissioners in Lunacy, 92,067 people in England and Wales alone. How many more there were unregistered no one can tell. That it is a large number is certain. That it will increase and is increasing I think there can be no doubt; for the public in general resents and resists the new and cumbersome Lunacy Law to the utmost of its power, and will continue to do so. The consequence is that patients are treated at home and are not registered, and the early treatment, which is admitted by all to be essential to recovery, is but rarely adopted. A controversy exists, and has existed for many years, as to whether insanity is increasing or not. We read in the Commissioners' Report that the number of registered lunatics and idiots in 1894 exceeded that of 1893 by 2245; but this, we are told, can be easily explained, and is no proof that insanity is increasing. My own belief is that we can deduce but little from such figures. If insanity does not increase it is to be inferred that the recovery-rate and the death-rate must decrease to account for this large accumulation of cases. I have nowhere seen any statement that insanity is decreasing, or that nervous disease is diminishing in frequency or intensity; and *a priori* reasoning would lead us to think that the reverse is the case—that the environment in which we live is becoming more and more complex, and that there must be a corresponding complexity of brain centres and functions with more and more instability and liability to disorder and deterioration. I know that this view has been called pessimistic, and that there are some whose opinions I greatly value who deny that there is any increase of complexity, and who point to brilliant men who live and are well in spite of hard brainwork. This does not, in my opinion, disprove my position, but only shows that the strong and the naturally selected escape the dangers which overwhelm the weak, who by natural inheritance and less fortunate environment succumb to nervous disorder. I shall come back to this part of my subject presently, when I speak of the rearing and training of those who are threatened with nerve or mind trouble. I wish first to say something about the great cause of insanity—hereditary taint. There is no need for me to argue before an audience like this upon the existence of such a cause of insanity or to raise any question as to the transmission of the disease by inheritance. Few medical men, even of those whose practice does not lie amongst the insane, can pass many years without its being brought under their notice. Young persons of both sexes break down, we know not why. The parents may assign this or that as a reason, but they are keeping back the true cause. The patients are too young to have acquired insanity; they have not been exposed to the changes and chances of life; they have not known the cares and anxieties of poverty and the condition of those who have to support a family on very small means; they have not failed in business or been disappointed in their ambition; they have not taken to drinking; their insanity is idiopathic, constitutional—derived from their forefathers; and insanity is inherited not only from insane parents, it may come from those who are afflicted with other nerve disorders, as epilepsy or dipsomania, and along with insanity we find in a family the disorders which I have

¹ Lectures I. and II. appeared in THE LANCET of April 6th and 13th respectively.

named and all the series of neuroses with which you are familiar. But statistics of inherited insanity we do not possess. Statistics of cancer, statistics of phthisis, two other hereditary diseases, we are able to arrive at and to argue upon. The reason of this is that cancer and phthisis kill their victims, and the record appears in the Registrar-General's list of deaths. But insanity does not kill except in a few cases. People become insane and may live for years in this condition, dying eventually from some other disease, which is tabulated as the cause of death. Two patients have lately died under my care. One, a woman, had been in the same asylum for fifty years. She died from an apoplectic seizure; the other, a man, had been forty-one years in the asylum and died from prostatic and bladder trouble. Not deriving any assistance from the Registrar-General, we are driven to the information we get from the relatives of patients and our own knowledge and observation. The former—the facts imparted by friends—are absolutely untrustworthy. That insanity exists in a family is denied with the most unblushing boldness. I recollect the case of a gentleman who was about to be married. The relatives of his intended heard in some way or other that his family was not altogether free from this disease, and they put some plain questions, not to him, but to his relatives. They were told in the most positive terms that nothing of the kind existed, though at the very time the gentleman was the committee of an insane aunt, and other suspicious cases had occurred. The marriage took place. Within six weeks the gentleman was in a foreign asylum. He recovered, again to break down, and after a series of recurring attacks he died in an asylum in three or four years a hopeless epileptic. Fortunately there was no issue of the union.

Mr. Francis Galton, who has, as you know, studied the question of heredity, tells us in his book on "Natural Inheritance" that when he issued his inquiries as to the "Records of Family Faculties" insanity was not asked about, as he did not think it wise to put too many disagreeable questions. No doubt he thought that the answers he was likely to receive on this point were not likely to add much to our knowledge. Without information, and accurate information, we can do little by dint of our own observation. There are but few of us who have the opportunity of observing many families through three or more generations. Here and there we come across certain insane persons in a family, and may be aware that in the preceding or following generation there have been others. But for the purposes of our investigation we want to know not merely these black spots and blights in the family tree, but the history of all the others, the half insane, the neurotic, the phthisical, the healthy. Is the family tending to decay and extinction, or is it reviving, throwing off its unhealthy branches, and with recuperated vigour ascending again to its proper racial place? We want to know the conditions of the one or the other of these terminations. Doubtless the environment has a good deal to do with the result, but inheritance has as much or more, and this is a matter more under the control of the interested parties if they will only suffer themselves to be controlled by our advice.

We may roughly divide insanity into that which is inherited and that which is acquired; but no one cause of acquired insanity at all equals heredity as a producer of mental disease. If we could stamp out all the insanity which owes its origin to inherited instability we should have gone a long way towards the extirpation of insanity as a whole, for a great deal of the mental breakdown which is apparently acquired is due to hereditary weakness. A large amount may be acquired through alcoholic indulgence; but if we closely examine the cases where alcohol is the exciting cause, in how many we find hereditary predisposition. Sometimes the alcoholic craving is inherited or it may come from ancestors who were not themselves inebriates, but showed some other form of mental or neurotic disease. Again, look at the insanity which is due to overwork or worry, to shock, disappointment, or religious excitement. Some such exciting cause may be found in many cases, but behind it we may perceive a predisposing cause, hereditary taint. How many a patient who is said to have suffered from worry has evolved his worry out of his own nervous, fidgety constitution. The things which are worries to him would be nothing to a more stable mind. And the same with work. What is healthy occupation to one becomes a burden too heavy to be borne by another who collapses under its weight. The same with losses and shocks and with religious strain. If we wish to save our race from gradual mental decay, and not only to

preserve life from such ills as syphilitic diseases but to raise up a strong and vigorous breed of healthy men and women, it is absolutely necessary that more attention shall be paid than has been done hitherto to the selection of the individuals who are about to marry and reproduce.

If men and women were racehorses or shorthorns or greyhounds their breeding would be regulated, and all diseased or faulty stock would be carefully eliminated, and all in-breeding would be, as a matter of course, avoided. But being what we are, thinking only of ourselves and our own self-gratification and nothing of the future race, we arrange our own unions, and nobody has the right or the power or the courage to prevent us when we have attained to years of discretion—viz., the statutory age of twenty-one. Many have thought and more have hoped that some day legislation may concern itself with this subject and prevent the union of persons one of whom has been insane or is specially threatened with the disorder. Vain hope. Legislation will not even annul the bond which ties a man or a woman to a partner, perhaps quite young, who is hopelessly insane and will remain so for the space of a long life. We can only trust that by education, by continual ventilation of the subject and exposure of the evils arising from its neglect, public opinion may in process of time be directed towards it, and people will be forced to look upon the act of giving birth to an insane child as a cruel sin. If we examine a family in which insanity exists—where, for instance, one or other of the parents has shown symptoms of mental disorder—we shall probably find that not all the children become insane; indeed, the majority may escape altogether. This may be due partly to a better constitution inherited by some than by others from healthy forefathers, and partly by the environment of some being more conducive to mental health than that of others. But it is impossible to forecast with certainty what will be the fate of this or that child. Some may break down early at puberty or adolescence, while others may show no indication till they attain old age; nay, they may escape altogether, and yet in the next generation the inherited taint may show itself.

For the prevention of insanity we would, if we could, forbid the marrying of unsuitable persons, persons who by reason of inheritance or being themselves neurotic or unhealthy or inebriate are likely to have diseased children. If there is insanity in the family we shall have to consider in how many members and in how many generations it has shown itself. If it has occurred in one of the parents, what was the age of the parent at the time of its appearance? Did it appear when the parent was young, at a time when it must obviously have been inherited, or did it manifest itself later in life with a cause and a history which showed it to have been acquired? What was the age of the parent when the child was born, and was it born before or after the disorder commenced in its parent? If the taint appears to be slight and the individual is strong and healthy and free from all neurotic symptoms, we then have to look at the other side of the union, at the partner that he or she is about to take. If this one's family history is absolutely free from inherited disease and the individual is sound in body, no great opposition can be offered if he or she is willing to undertake the risk, but that there is a risk ought to be clearly explained. On the other hand, if there is a taint of insanity on this side also, if the parties are cousins or either is eccentric, nervous, weak-minded, ultra-religious, or ultra-emotional, the union should be forbidden, not only on account of the offspring, but for the sake of the parties themselves. The effect of the knowledge of this family disorder may have a disastrous influence on their lives and may cause the greatest misinterpretation of actions and trial of tempers. Whatever difficulty we may experience in advising as to the marriage of those in whose families insanity exists, there will be much less when we are consulted about men or women who have already had an attack of this disorder. When the individual is a girl we are at once confronted with the popular and prevalent idea that marriage is a cure and sovereign remedy for such disturbance, and advisers, even medical, say to the parents, "get her married." They think this will cure any remnants of the past attack and be a certain preventive of any in the future. Our advice on the subject is often taken and but rarely followed. The attack will be concealed from the knowledge of the other party, if this is possible, or will be minimised and spoken of as nervous or hysterical, or it will be denied altogether. I hold a strong opinion that people who have been insane ought not to marry at all, that they ought not to inflict on their

partner for life the anxiety and even danger of another attack. No one who has had one attack of insanity can be pronounced free from the risk of another. Insanity is a disease which confers no immunity on its victims like some we have to treat. On the contrary, each attack, if there be more than one, adds to and does not take away the liability to succeeding ones, in this respect following the example of its congeners such as epilepsy or neuralgia. And besides the risk and danger to the partner in the marriage there is the question of offspring. In this there is far greater danger for the woman than the man, for the former has to face the periods of pregnancy, parturition, and it may be lactation, and what numbers do we see who break down after childbirth who had they remained single might have led a happy and a useful life.

Patients and their friends when recovery takes place from an attack of insanity fondly imagine and flatter themselves that they will never have another. They rake up some little circumstance which they think was the cause and argue that it will not occur again; and if they ask us our opinion on the subject it is not easy for a physician to say to one just convalescent and rejoicing in the return of reason and hopeful of the future—it is not easy to say to such a one: "You will surely break down again; you will be as bad as you have been lately, and you should shape your life with this idea ever before you." It would be thought very hard, injudicious, and unkind were we to say this; so we let our patient go and make him or her happy. Nevertheless we ought to advise that no marriage should take place and set before the friends the risks thereof. People with this tainted inheritance do, however, marry without advice, very often in spite of it, and when married they break down, recover perhaps, and break down again. The wife may have puerperal mania at one or more of her confinements, the husband may show symptoms of the disease at an early period. Now, holding the opinion that I do as to the necessity of preventing inherited insanity, I must say that in my judgment people who have had attacks of the disorder ought to have no more children. What can be more lamentable than to see a woman break down in child-bed, recover, break down again with the next child, and so on for six, seven, or eight children, the recovery between each being less and less, till she is almost a chronic maniac? I have known this to occur more than once, and doubtless some of you have had a similar experience. For the sake of the mother and the father, to say nothing of the children, there ought to be an end of their begetting when insanity follows the birth. I have a case in my mind where this succession of attacks occurred a number of times—six or seven at least. Both parents—father and mother—died in an asylum. There was insanity in both the father's and mother's family. The children are growing up. The eldest developed dipsomania at an early age. What the others will develop remains to be seen. I do not confine these observations to cases where the mother has become insane after marriage. The same applies to fathers who have had attacks of insanity. There is not, of course, the same personal risk to the father that there is to the mother—the risk of dying in an acute attack of puerperal insanity or of becoming through such an attack permanently insane; but there is the same risk for the children—the same chance of bringing into the world a progeny which shall hand on this heritage of insanity or all the other varieties of neurotic disease.

After hereditary transmission there is probably no cause of insanity which exercises so potent an influence as alcoholic drink. To estimate the extent of this we must go to the reports of the medical superintendents of our pauper asylums, many of whom mention it as bringing a large proportion of patients under their care. The proportion differs much according to the locality and the class of population from which the patients are drawn. As we go from south to north the numbers increase, Cornwall, Devon, and Dorset furnishing the least. These are for the most part agricultural counties, with few large towns. When we examine the reports of asylums in the midst of large manufacturing towns or mining districts the numbers increase, for wages are higher, habitations and life unhealthy, and drunkenness prevalent. And it has been observed that the admissions from this cause are more frequent when trade is good and wages high. When the reverse is the case or when strikes diminish the spending power of the workman the number of the admissions falls. So long as drinking remains as it is it will be impossible, I think, to say that insanity is diminishing, at any rate among the lower classes. The spread

of temperance principles, the advance of education, the improved sanitation of dwellings and workshops, and the influence of wholesome recreation for the mind as well as the body will, we must hope, gradually check the drinking that at present prevails; but I must not take up your time by dilating on this subject. That drinking has greatly diminished among the educated classes is beyond a doubt. A certain amount of insanity is produced still by alcohol, together with alcoholic paralysis and dementia, but there is far less among the higher than among the lower classes. The proportion, however, of drinking women is, I fear, greater among the former than among the latter. If we look at the statistics of our public asylums the number of males whose insanity is caused by drink largely predominates, but of the alcoholic cases brought under our notice in private practice a very large proportion are those of ladies. And this will be the case till legislation enacts that such shall be compulsorily detained in inebriate resorts. At present scarcely one will place herself under care and treatment, and the Act is almost a dead letter so far as women are concerned.

From time to time we may have it in our power to give advice concerning the bringing up of threatened children, the children of parents in whose families insanity exists, or who have already themselves shown symptoms of the disease. If the insanity is on the mother's side the child should not be suckled by her, but should have a good wet-nurse. And this for two reasons: the mother's nights should not be disturbed by having to wake and nurse the child; and, secondly, a good wet-nurse is more likely to efficiently nourish it. Nourishment is most essential, and such a child is favourably placed if it is fat, and is badly off if thin. This will depend not only on food, but also on sleep. Of this it cannot have too much. It should be encouraged to sleep as much as possible and at regular times, so that the habit may be engendered and adhered to, and this sleeping—sleeping by day as well as by night—should be kept up for many years, till it is five or six years of age. Children who have plenty of food and sleep are not likely to be troubled by fits or convulsions, but if any should take place they are of grave import, and the cause should be carefully looked for and, if possible, the evil averted. Some nervous children are troubled by nightmare, "night horrors." Judicious care and soothing are needed, judicious treatment by day and the rigid exclusion of all terrifying subjects such as ghost stories, tales of robbers or spectres, threats of bogies or policemen, and the like. Parents are often little aware of what goes on in the nursery behind their backs and what harm their children are deriving from those placed in charge of them. They may be even taught habits of self-abuse by nurses in order to keep them quiet; and their treatment by parents may be equally injudicious if the latter are themselves peculiar and extreme in their views, violent in temper, or capricious. They may spoil them at one time by indulgence in food or drink, they may frighten them at another by intemperate quarrels and noise, or they may dose them with religion till the children loathe it or become the veriest little hypocrites. Dr. Clouston tells us of a little boy aged four "who by dint of constant effort on the part of his mother was so sensitive as to right and wrong that he never ate an apple without first considering the ethics of the question as to whether he should eat it or not; who would suffer acute misery, cry most bitterly, and lose some of his sleep at night if he had shouted too loud at play or taken more than his share of the cake, he having been taught that these things were 'wrong' and 'displeasing to God.' But the usual amesthesia that follows too keen feeling succeeded the precocious moral intensity in this child, for at ten he was the greatest imp I ever saw, and could not be made to see that smashing his mother's watch, or throwing the cat out of window, or taking what was not his own, were wrong at all." The egotistic nature of those who inherit the insane diathesis I have already mentioned, and this ought to be kept in view in the education of all children born with such a lot. There is much in home life to encourage such egotistic selfishness. It may be an only child or the first child, possibly a delicate child requiring much watching and care. It is easy to foster this selfishness, and much caution should be observed to avoid so doing. The child should have the society of others, should be taught to consider its playmates first and itself last, to share its toys and luxuries, and be good-natured and generous. It should be taught to be considerate towards servants, to be kind and not cruel to dumb animals. Cruelty

to the latter is a constant concomitant of weak mind. School, even at an early age, is a benefit to many such children—girls as well as boys. They are taken away from the injudicious spoiling of home, and are compelled to consider their companions and not themselves. They have to obey orders, to observe proper hours, to learn discipline and regularity, all of which may be novelties to them. To many the first going to school is a veritable plunge in a cold bath, but like the latter is highly bracing and wholesome.

There are two sorts of children about whom we may be consulted—the dull and backward and the preternaturally sharp and precocious. The first may not be an idiot or imbecile, but may be backward, slowly developed, and at the age of twelve may approximate in capacity to a child aged seven. Such a one requires special tuition and treatment. It is useless to place him in a form of other boys of the same age and expect him to do the same lessons and compete on the same terms with the others. Still worse is it to punish an unfortunate boy of this class because he does not know his lessons and to set him down as lazy or idle, and cane him because he is dull and accounted as obstinate. Incalculable harm may be done to a boy or girl by mistakes of this kind. The education must be fitted to the capacity, and the tutor must discover whether such a child has a special aptitude for any one branch of knowledge—music, drawing, carpentering, or mechanical engineering. It often happens that there is some latent talent which is well worth cultivating. Then there is the precocious boy—bright, intelligent, quick to learn, the pride of his teachers. If he goes to a private or preparatory school he will be seized upon as one who will win scholarships and bring glory on the school, and he will be crammed for this purpose and will have to contend at the age of twelve or thirteen against a host of other little victims at one of our public schools. I have marvelled at the amount which can be crammed into a boy at this early age. But if a hundred contend for ten scholarships it is obvious that ninety must return empty handed, and these children must at this early age undergo the disappointment of failure. The evils of continual examinations have attracted the attention of many besides the members of our profession. Some six or seven years ago Mr. Auberon Herbert drew up a protest against the system which now prevails, the spirit of place-getting and prize-winning in education, and the dominant position assigned to examinations. It protested against the evils resulting from the intellectual racing of boys and girls against each other, and warned parents that the physical ill-effects were often not disclosed at the moment. It laid special stress on the harrowing and depressing effect which reading with a view to satisfy the examiner's mind necessarily has on the student. It spoke of the hurtful consequences of this, of the temporary strengthening of the rote-faculties to the neglect of the rational faculties, the rapid forgetfulness of knowledge thus acquired, the cultivation of a quick superficiality and power of skimming a subject, the consequent incapacity for undertaking original work, and the desire to appear to know rather than to know. I cannot quote this at length, but it was printed in the *Nineteenth Century* in 1888. Many agreed with it, for it was signed by some hundreds. Amongst them were 377 teachers, including many university tutors, the headmasters of many schools, and no less than 130 ladies who were concerned with the education of girls and cognisant of the evils produced by the sacrifice of education to examination. And besides the teachers it was signed by 62 members of our own profession, including some well-known Fellows of this College. Mr. Herbert has also published not only the names of the signatories, but also between 200 and 300 letters from those who have expressed to him their views on the subject. They bewail the evil, but many do not see clearly what is to be substituted in place of examinations, especially the competitive examinations for Government appointments. The headmaster of Eton says that if the system of competition by examination cannot be altered the conditions of examination can be ameliorated. He speaks of the great increase of the number of boys wearing spectacles, even at Eton. "Many a bright, keen intellect of ten to twelve," he says, "has become dull and blunt and has lost its temper by fifteen or sixteen owing to over-preparation with a view to scholarships." The headmaster of Wellington College is equally severe upon the evils of the competitive system. "It seems to make real education, wholesome development of the natural tastes and faculties, impossible. It kills originality and even intellectual interest. We live in

a hurry which allows no knowledge to root itself." And if the evil is great for boys it is ten times greater for girls. Many boys are compelled to go in for examinations, for those "abominations," as one gentleman calls them, the Civil Service and Sandhurst drill. But very few girls are. Few have to earn their livelihood in some walk of life to be gained by competitive examination, and of many of the prizes thus to be gained it may with certainty be said that the game is not worth the candle. We ought not to treat knowledge as a commercial commodity. Nothing nowadays is to be learned unless it will pay, unless it will tell in an examination, and is to be estimated at a pecuniary value. And this is not confined to the middle and upper classes. Says one gentleman: "Every child, the weak or the strong, regular or irregular, who enters an English elementary school is a grant-earning machine. To get the highest grant all must be brought up to the same level in the allotted time. It follows, therefore, that children of naturally slow development must be more or less overtaxed, to the permanent injury of their brain power, and that the bright, intelligent, healthy children have to 'mark time' in their studies while their less gifted fellows are crammed with the necessary amount of knowledge. What are the results? Children are passing out of the State-aided schools of to-day by thousands without having gained a love of learning—in fact, with a positive dislike of acquiring knowledge."

Gentlemen, I have seen—I feel certain that many of you have seen—disastrous effects from pressure of examinations upon boys and girls. They are crammed for examinations; they fail to pass, or fail to gain the prize for which they are competing. The end of all the long and wearisome toil of cramming and grinding is failure. Conceive what this means to the young and developing brain and mind. Many break down in the mere preparation and never get to the examination point. One boy I certified, for it was necessary to send him to an asylum, who had been kept for hours and hours practising the violin. I do not even know that there was any intention of making this boy a professional player, but his father was musical and wished his son to be a proficient. A girl I saw had been practising an equal number of hours daily on the piano to pass some examination or win some prize at the Academy of Music. Not only is there a rage nowadays for competitive examinations, and every school and college and other educational institution must hold out a number of money prizes as baits to catch pupils, but the ordinary pass examinations are divided and subdivided till their number is multiplied indefinitely, and the student has constantly in front of him an examination in some subject or other on which for the time he must concentrate his whole mind, but which is to be completely thrown aside as soon as it is passed, when another has to be taken up in its place. A student's career in our own profession, for example, has not for its aim the acquiring of knowledge, but the passing of examinations. He has no time for the study of disease at the bedside. His knowledge of disease is got out of text-books, or after his examinations are over he must begin by post-graduate courses to learn something about it. Where all this subdivision will lead to at last it is difficult to see. Be it remembered that I commenced by speaking of the education and rearing of the weakly, of those who by reason of a faulty inheritance are likely to succumb to an over-pressure which may not be hurtful to the strong. It is no argument against the evil of such over-pressure to point to the strong, to those who by constitution and favouring circumstances rise without stress or difficulty above their fellows. That there are many such among us we know, and are glad thereof—men who can row in the eight, play football and cricket, and take a first class; but my subject is the prevention of insanity in those predisposed to it, and these are not to be treated like the strong. Unless care is taken the end may be that of a young man who was under me some few years back, who achieved five first classes at Oxford and died from general paralysis at thirty-seven. Weak by constitution, and having an inherited taint, he developed organic brain disease by over-exertion.

In the bringing up of the predisposed several things must have special attention. The first I will mention is the importance of not subjecting such children to narrow and fanatical views of religion. Self, self-inspection, the perpetual consideration of self, are among the characteristics of incipient insanity, and to encourage all this is manifestly the worst thing that can be done. Children suffer terribly in this respect from narrow-minded and bigoted parents who,

convinced that they are right, seek to force upon their offspring their peculiar ideas, and often bring about a hatred of everything religious, if they do no worse. How often has one seen at school that the worst and most vicious young scapegraces were the sons of rigid, uncompromising clergymen. At home such boys are kept so free from vice and in such ignorance of what it means that when turned loose in the freedom of school life they revel in the new-found pleasure and drink deep, regardless of the consequence. Another effect is to make these children dreadful little hypocrites. They have to play a part at home, not daring to divulge their true likes and dislikes, and I have seen long pious letters and pious poems from a girl written to such parents when, as I happened to know, she was as wicked and depraved as any I have met. The next thing to be guarded against is the habit of self-abuse. Children have been taught this by nurses in order to keep them quiet and make them go to sleep. They may also be taught it by other children. I have been told by some women that they have found it out by themselves. I am aware that much nonsense is talked with regard to this habit. Parents who wish to conceal the insanity of their family are ever ready to assign self-abuse as the cause of an attack in one of their children if it can be shown that the patient has ever indulged in this vice, no matter how rarely. Great harm, too, is done by exaggeration of the consequences, as is so frequently seen in the literature disseminated by all the tribe of quacks who prey upon the nervous and frighten them with the hobgoblin of spermatorrhœa and the like. The neurotic, however, are those most likely to suffer from the habit and most prone to indulge in it to excess, and there can be no question that it causes insanity in not a few. Many boys, I feel sure, contract the habit without knowing that any harm can come of it. Ought boys to be warned against it or not? A discussion on this question took place at Bristol last summer, and opinions were given for and against it. My own belief is that boys should be warned, but not girls, who are far less likely to be taught it by others. Since the Bristol meeting my view has been confirmed by the headmaster of one of our chief public schools, who has requested the parents of the boys to take care that their sons are warned against the practice. The habit, if already contracted, should be stoutly resisted, and hard exercise and play, plain living, and the absence of stimulating food and drink should be inculcated with this view.

It would be a good thing if all boys and girls with an hereditary taint were brought up to abstain totally from alcohol. There is always a risk of these neurotic individuals taking to drinking. What is insanity in one generation often appears as inebriety in the next, and they are not likely to give up easily such a habit and craving if once established. Often inebriety is directly inherited. I lately saw a young man aged twenty-four who was emerging from an attack of delirium tremens, one of many he had already had. He began to drink hard at the age of fifteen. His father and mother both drank themselves to death and the son was following their example, and we have at present no law to prevent him. Such young people should be taught to abstain. It will be no hardship if they have never known what wines and spirits are, and they should be made clearly to understand and recognise the reason why such abstinence is enjoined. It is far easier to abstain from childhood than to revert to abstinence in later life.

When boyhood is passed the young man has to choose a profession, and the young woman also, perhaps, has to seek a livelihood in some walk of life. Great are the difficulties which lie in the way of either. The young man is beset almost everywhere by the terrors and evils of competitive examinations. Truly our forefathers were exempt from difficulties which surround us. Appointments could be obtained in the various branches of the Civil Service which offered a steady career pre-eminently fitted for nervous youths, where hours were short, the work light and free from anxiety, and holidays long. Nowadays these posts can only be got by competition. Then there was the army, which was adapted to others. A commission could be bought, and if the lad was not fit for foreign service it could be sold. Now a severe examination has to be passed before Sandhurst can be reached, and many fail and are disappointed after years of cramming. For lads who were not studious and liked an out-door life farming had charms and a livelihood might be earned by the cultivation of the soil; but who at the present time would

bring up his son to farm land in this country and climate? Nay, it is difficult to choose a profession for a lad with a nervous inheritance, even if he has plenty of brains and can pass examinations with ease and credit. Take the Civil Service of India, which, I suppose, is the highest prize to be gained by examination. It by no means follows that the lad who is able to gain a high place in this is best fitted to be an Indian civil servant. If he is one of the clever but nervous individuals of whom I have been speaking, he will have to face the dangers of a tropical climate, perhaps in a very unhealthy place. He will have great responsibility at a very early age, for "he may have to administer a district with a population of thousands of human beings. He has to deal with races a large number of whom are highly intellectual, and their management and contentment require not a man of mere ill-digested knowledge, but thought, judgment, self-restraint, and propriety."² Many young men whom I have known have succumbed to the climate and the work, and have been obliged to abandon the service. I hold the Indian climate to be extremely dangerous to all who inherit a predisposition to neurotic disease. The same may be said of our army and of those who, successful in examination, pass into the line. Formerly one met men who had passed their lives in the army without ever having been in India. In the days of the East India Company our own regiments did not go there in the numbers they do now, and we kept troops in colonies where now there are none. Now all our soldiers have to spend a considerable time in India or, what is worse, in Burmah, and many come home suffering from brain disorder. My own opinion is that no one who has had an attack of insanity ought to return to India, and I know the authorities are disinclined to allow them, but if they cannot they are practically shelved. The professions imply examinations, hard work, perhaps long waiting and little success. The Church is not suited for a neurotic man. It is an emotional life. He may have difficulties of belief, doubts and scruples of conduct. He will see much sickness and suffering which he is powerless to relieve. It is not difficult to point out the occupations which are unsuited to the neurotic man; it is more difficult to say what is the most suitable. That will be best which entails least worry and responsibility, which does not involve money losses or troubles, or great and sudden disappointments. Moreover, it is very important that every man should have beyond his everyday work some amusement, pursuit, occupation, or hobby—call it what you will—which shall be a relief to him after his daily task, a paragon or by-work, as Plato calls it, which shall be at once a food and a rest to his mind. A man's daily task may be a very monotonous and routine business, which is not enough to occupy a healthy brain; on the other hand, it may be anxious and worrying. In either case it is good for that man to leave his business behind him at his office and devote his energy to something else at home. If we look through the lists of our learned societies—the Antiquaries, the Linnean, the Entomological, the Geological, nay, even the Royal—how many names do we find of busy men engaged in daily work—city men, solicitors, clergy—who refresh and recreate their minds with these studies and pursuits; and how often do we find a man in business break down, and hear that, apart from his business, he has no thought, no occupation, no amusement. He goes to business early and returns late, and the morning and the evening newspaper are all that he reads from Monday morning to Saturday night. Of the occupation best fitted for women I can say but little, for time forbids. It is easier, I think, to find work for them than for men. But that which so many nowadays wish to take up—namely, nursing—is most unsuitable. Nursing is for the strong, bodily and mentally. It involves great anxiety, great responsibility, and loss of sleep, and therefore is the last calling which the predisposed should follow. When he has chosen or entered on a profession, and very often before he has done either, the young man falls in love and wants to marry. He is not likely to consult our profession as to whether he shall do this, or if he consults us he will not follow our advice unless it should happen to agree with his own wishes. In many cases where the predisposition is strong and the individual manifestly unhealthy and neurotic, we should certainly advise him to abstain, especially if his means are small and pecuniary difficulties are sure to arise if a wife and family have to be kept.

² Sir W. Gregory.

These young men generally become engaged first, and then come and consult us as to whether they ought to marry. Were they to ask our advice before they have set their hearts on any particular girl, we should advise them to be sure and select one who was free from all tendency to neurotic disorder and in whose family nothing of the kind has existed. Not an easy thing to discover, I grant, owing to the secrecy with which such a history is concealed; but if a man is prudent and not over-hasty he may learn a good deal of a family before he proposes to contract a marriage with one of its members. And above all, let him avoid a connexion with one of his cousins, for if there is a latent taint it will be intensified by such a union. Marriage for a woman is still more serious than for a man, for she has before her child-bearing with all its dangers. Some women with feeble health and frail physique we should certainly advise never to marry. All who have insanity in their families marry at their peril, and those are the best off who have no children. Such women certainly ought not to marry poor men and have the additional burden of narrow means, the care of a family with but little help, and the ever-present cost of medical attendance and nurses.

Can a man or a woman do anything towards preventing insanity? This is a question sometimes put to us, more frequently, however, with regard to the prevention of a recurrence by those who have suffered from an attack. In many young persons the insanity occurs at so early an age, and is so manifestly due to inherited predisposition, there having been no trouble, sickness, or anything perceptible to cause it, that it is to be feared that no advice that we can give will enable the individual to escape the malady. Nevertheless, the direction to be observed it is not hard to point out. We have seen that in insanity there is an exaggeration of the self or subject consciousness and of the egotistic feeling, which rises to a morbid state when the mind is diseased, but may exist in a less degree in a person who is not insane but is of an insane temperament and predisposed by inherited taint. It is important that such a man or woman should correct as far as in them lies this tendency to egotism and selfishness, should not give themselves up to thinking only of themselves, to brooding over their troubles, paying attention only to their own health, and caring only for their own gratification and pleasures. That this self-consciousness often ends in insanity we know, and from *a priori* reasoning we should expect it so to do. It is clear also that in such a case there is no adjustment of the individual to his surroundings, and this is what constitutes insanity. We see what direction a man ought to take to lead a healthy mental life; that he must not live for himself, but take thought for others, feel sympathy with others, and help and defend others. He must adjust himself to his surroundings, and not strive to adapt the latter to his own whim and wish. All this may be difficult for a man suddenly to do who has never done it hitherto. It is less difficult to train a child in this direction, for it is the direction in which all children should be brought to walk, and more especially those who are predisposed to neurotic disorder. One has seen such at school—eccentric boys who are peculiar in their dress and ways, clever perhaps in some things, but erratic and unsatisfactory. Such boys are rarely gregarious. They do not adjust themselves to their surroundings, but lead for the most part solitary lives, just as the insane do. They amuse themselves alone and nobody knows much about them. It is one of the great advantages of the enforced games at a public school that a check is put thereby on the solitary wanderings of such boys, and for a time, at any rate, they have to congregate with their fellows.

In conclusion, Mr. President and Censors, I beg to thank you, first, for the honour you have done me in appointing me the Lumsden Lecturer for this year, and, secondly, for the patience with which you have listened to my imperfect discourses.

THE Duke of Westminster will introduce a deputation of the Church Society for the Promotion of Kindness to Animals and the Church Sanitary Association to the President of the Local Government Board on Monday, May 27th, asking that in conjunction with the Board of Agriculture a joint departmental inquiry may be instituted by which may be brought about, on the one hand, the betterment of the condition of animals generally, and, on the other, the improved health of the human community as the result of improved conditions of meat supplies.

THROMBOSIS OF THE INTRACRANIAL SINUSES SECONDARY TO SUPPURATIVE DISEASE OF THE MIDDLE EAR.¹

BY WILLIAM MILLIGAN, M.D. ABERD.

SENIOR ASSISTANT-SURGEON TO THE MANCHESTER INSTITUTION FOR DISEASES OF THE EAR; LECTURER UPON DISEASES OF THE EAR, OWENS COLLEGE; AND ASSISTANT PHYSICIAN TO THE MANCHESTER HOSPITAL FOR DISEASES OF THE THROAT.

ONE of the most important and at the same time most dangerous of intra-cranial complications secondary to suppurative disease of the middle ear is thrombosis of the venous sinuses. Any or all of the sinuses in immediate relation with the temporal bone may become thrombosed as the result of infective middle-ear disease, but the one most frequently found implicated is the sigmoid sinus. The relation of this sinus to the mastoid antrum, mastoid cells, and middle ear will at once offer a ready explanation of this fact. The intervening bony septum between the antrum and the sinus is frequently very thin and perforated at numerous points for the passage of small veins along which infective material is readily transmitted. Septic infection in such cases is preceded by the formation of an extra-dural abscess. In like manner the bony septum intervening between the floor of the middle ear and the jugular bulb is so thin and so riddled with vascular foramina that septic products and pyogenic organisms are readily conveyed to the jugular sinus, with the result that septic thrombosis is readily induced. The petrosal sinuses, both superior and inferior, and the cavernous sinus may likewise become affected, either as the result of direct extension from the middle ear or indirectly from extension of an already existing thrombosis in one of the other intracranial sinuses. Septic thrombosis is as a rule the result of prolonged infective disease of the tympanic mucous membrane and its adnexa, although at times it does occur as a consequence of acute diseases affecting the mouth, pharynx, tonsils, &c., in which rapid extension to the middle ear has taken place along the course of the Eustachian tube. When occurring in the course of chronic suppurative middle ear disease it is usual to find extensive changes in the surrounding bony parietes. This osseous erosion is induced in consequence of the prolonged suppurative disease of the tympanic mucous membrane, which serves the double function of mucous membrane and of periosteum. In rare cases no bone lesion is discoverable, the infective products having been carried directly along the numerous vascular channels existing around the middle ear. Thrombosis of the lateral sinus is most frequently found between the ages of twenty and thirty. It is rare in children and old people. The male sex would appear to be more frequently affected than the female. It is a point worthy of note that in the male thrombosis is most frequently right-sided; in the female, according to Robin, it is most frequent upon the left side. Sinus phlebitis runs a somewhat irregular course. At times death takes place rapidly from exhaustion and collapse; at other times, however, pyæmic metastatic deposits occur in the lungs, liver, kidneys, spleen, joints, &c., and death ensues from gradual loss of strength and marasmus. In other cases, again, a fatal issue may be induced as the direct result of the toxic effect of the pyæmic blood upon the central nervous system or may simply be due to hyperpyrexia. The diagnosis of septic thrombosis is at all times somewhat difficult and frequently is merely a diagnosis of probability. Thrombosis may, however, be fairly assumed to exist if in the course of chronic suppurative middle-ear catarrh there is a sudden cessation of discharge accompanied by persistent pain in and around the ear, a high temperature with marked fluctuations and frequently repeated rigors, vomiting, rapid pulse, and constant headache. Ballance² in an able article states that the following group of symptoms occurring together are pathognomonic of the disease: (1) a history of a purulent discharge from the ear for a period of more than one year; (2) sudden onset of the illness with headache, vomiting, rigors, and pains in the affected ear;

¹ A communication made to the Manchester Medical Society on Dec. 5th, 1894.

² THE LANCET, May 17th and 24th, 1890.

(3) an oscillating temperature, reaching from 103° to 105° F. and then dropping below 100°; (4) vomiting repeated day by day; (5) a second, third, or more rigors; (6) local oedema and tenderness over the mastoid or in the course of the internal jugular vein; (7) tenderness on deep pressure at the posterior border of the mastoid process and below the external occipital protuberance; (8) stiffness in the muscles of the back or side of the neck; (9) optic neuritis. It must not be forgotten, however, that infective sinus thrombosis may exist along with other intracranial lesions—e.g., abscess or meningitis. Thus we may have cases of thrombosis: (1) with meningitis, (2) with intracranial abscess, or (3) with meningitis and abscess. In such cases the symptoms due to the thrombotic process usually, however, gain the ascendancy, and may mask other lesions of equally serious import. The difficulties of determining at times which is the predominant intracranial affection are so great that in every case where doubt exists it is advisable to follow a definite course of operative procedure. Such a course has recently been mapped out by Urban Pritchard² and consists in: 1. Thoroughly opening the mastoid antrum and exploring the mastoid cells. 2. Failing to find sufficient evidence to account for the whole of the symptoms, the wound in the skull should be enlarged backwards so as to expose the middle and posterior cerebral fossæ above and below the lateral sinus, which should be explored by means of a hypodermic syringe. At the same time extra-dural abscesses may be carefully looked for. 3. If a clot be found in the sinus the internal jugular vein should now be tied, and the sinus opened and cleared of its contents. 4. If there is any suspicion of cerebral or cerebellar abscess exploratory puncture may be made above and below the sinus and the pus if found evacuated. The pathological changes which take place consist of a thickening of the coats of the sinus, desquamation of its endothelial lining, and formation of a thrombus. As the thrombosis is almost invariably infective in origin the clot rapidly undergoes disintegration, and the particles thus formed mix with purulent exudation formed from the inflamed walls of the sinus, with the result that small emboli teeming with micro-organisms are carried away in the blood stream to become impacted in the capillaries of some such distant organs as the lung, liver, or kidney, with the consequent formation of embolic abscesses. Within the skull and around the walls of the sinus plastic exudation occurs. This exudation rapidly disintegrates and forms a purulent layer of varying extent, or, in other words, leads to the formation of an extra-dural abscess. If, on the other hand, the visceral layer of the sinus be the one principally implicated, an acute infective lepto-meningitis rapidly ensues. This may remain as a local inflammatory affection in the neighbourhood of the sinus or may become generalised. The same process may happen in any one of the sinuses already mentioned. Thus, when the internal jugular vein has become thrombosed an abscess may be found in the neck; when the cavernous sinus the abscess may be found in the peri-orbital connective tissue. The bone in the immediate neighbourhood of the affected sinus undergoes certain marked changes. These changes consist in deep pigmentation and erosion of the osseous substance. Pigmentary deposits are also found upon the adjoining surface of the cerebrum in the case of lateral sinus thrombosis, upon the under surface of the temporo-sphenoidal lobe in the case of superior petrosal thrombosis. The systemic pathological lesions will depend upon the duration of the accompanying pyæmic process and upon the particular organ implicated. Thus in the case of the lung an infarction due to pulmonary embolism is produced. This rapidly disintegrates and a pulmonary abscess is thus produced. These abscesses may be multiple and small or may by coalescence occupy a considerable portion of a lobe. In the same way splenic and renal infarcts lead to splenic or renal abscesses with their accompanying symptoms. The differential diagnosis of infective sigmoid sinus thrombosis from such other intracranial complications secondary to purulent middle-ear disease as meningitis and cerebral or cerebellar abscess is as a rule not particularly difficult; but, as has been previously mentioned, thrombosis may, and frequently does, exist in conjunction with one or more of the above-named conditions, so that an accurate estimate of the cases is at times almost impossible, and hence the necessity of operative interference proceeding in definite order. In meningitis, which is usually suppurative in character, the temperature is high, and remains high, the pulse is rapid, of small volume, and frequently irregular. Symptoms due to meningeal irritation are also present—e.g.,

retraction of the back of the head, strabismus, &c. In abscess the temperature after the first rise falls either to normal or more usually becomes subnormal, the pulse and respirations are slow, and the cerebral faculties are dull and apathetic. In thrombosis, on the other hand, there are frequent and marked irregularities in the temperature chart, accompanied usually by recurring rigors, profuse perspirations, and symptoms of pyæmic involvement. The prognosis in such cases is necessarily very grave, and until within quite recent years the condition was looked upon as practically hopeless. The possibility that the thrombus may become transformed into connective tissue and by blocking the sinus prevent the dissemination of septic products through the system should not be too much relied upon. Most cases which are left to themselves terminate fatally. In 1886 Victor Horsley, in a paper read before the Clinical Society of London, made the very valuable suggestion that the internal jugular vein should be tied so as to prevent the dissemination through the system of the disintegrating and septic clot, qualifying this statement, however, by saying that the operation should be performed only when the first indications of embolism had appeared. More recent investigations have, however, shown that as soon as the diagnosis has been made operation should be undertaken. The earlier the channels along which septic emboli may be conveyed to more distant organs are shut off by ligature from the main blood stream, the better for the patient. Delay at this stage adds greatly to the patient's danger. The duty of the surgeon is clearly to add no element of risk to what may be fairly called a condition of extreme danger. In this country excellent operative work has already been done in this direction by Ballance, Lane, Bennett, Macewen, Parkin, Parker, and many others.

CASE 1. *Uncomplicated sinus thrombosis secondary to old-standing infective middle-ear disease.*—The patient, a young man aged twenty-five years, had suffered from right-sided, suppurative middle-ear disease for many years. Discharge from the ear had been almost continuous, although never very profuse. No pain had been complained of, nor had the patient ever suffered from tinnitus or vertigo. A few days prior to the onset of serious symptoms the patient had contracted a severe chill owing to being exposed on a particularly wet night and to his having been obliged to sit in wet clothes for some hours. This was followed by pain in the ear, radiating over the corresponding temporal region, and by a complete cessation of discharge from the ear. The pain having gradually increased, I was asked by Dr. Brown of Chorlton-road to see the patient

FIG. 1.

along with him upon the evening of Monday, June 18th, 1894. Upon examination the following notes were made. The aspect of the patient was pale and anxious, the skin was clammy, the tongue furred, the bowels constipated, and the urine high coloured. The temperature was 99.4° F., and the pulse 74. Examination of the right ear revealed a very small quantity of fetid discharge within the meatus. After syringing, the membrana tympani was found perforated in its posterior inferior segment. No granulation tissue was seen and no carious area of bone was detectable with the probe. Pressure over the mastoid process produced slight discomfort. The tissues between the angle of the

² Archives of Otolaryngology, vol. xxiii., Nos. 1 and 2.

jaw and the mastoid process were puffy, and pressure in this region was accompanied by severe pain. Careful palpation showed that either a chain of enlarged glands existed or that some fulness in the internal jugular vein was present, but which of the two could not be definitely stated. Dr. Brown, upon visiting his patient the same afternoon, had noticed a slight rigor, and this fact, in conjunction with the history and appearances of the ear, made me suggest the advisability of removing the patient to the Manchester Institution for Diseases of the Ear, in order that an operation might be performed the moment an accurate diagnosis could be made. The patient was accordingly removed the same night. The following morning the temperature was 100° and the pulse 86. The condition of the ear was as before. Boracic fomentations were ordered to be applied every half hour, and the ear was kept frequently flushed with a warm solution of bichloride of mercury (1 in 2000). Three grains of calomel were also given. The following day, June 20th, the patient had a well-marked rigor at 11.30 A.M., the temperature reaching 103° . At 5.30 P.M. there was another rigor, the temperature reaching 103.5° ; and at 10.15 P.M. the same evening a third rigor took place, the temperature reaching 104° . The pain in the head had by this time greatly increased, and the swelling in the neck had become at least twice the former size and was extremely sensitive to touch. Examination with the ophthalmoscope showed the existence of optic neuritis of the right disc, but no deviation from the normal upon the left side. The pupils were equal and reacted readily to light. As the position of the patient was now becoming critical it was decided that the best course to

small Volkmann's spoon was now introduced through this opening and the thrombus, which was partially adherent to the walls of the sinus, was scraped away. A quantity of pus and purulent debris also escaped. As the clot was removed from the torcular end of the sinus free hæmorrhage took place. This was immediately controlled by packing the open end of the sinus with iodoform gauze and iodoform and boracic acid powders. After as much of the clot had been scraped away as was possible the proximal portion of the sinus and the upper portion of the jugular vein were irrigated with a warm 1 in 2000 bichloride solution until the fluid escaped freely into the neck. The operation was now completed by extending the bone wound forwards until the mastoid antrum was freely exposed. The interior of the antrum, which was filled with granulation tissue and purulent debris, was curetted and a free communication formed with the middle ear. The parts were then carefully dried, dusted with iodoform and boracic acid powders, and dressed in the usual way. The subsequent history of the case was uneventful, the patient making a rapid and good recovery.

CASE 2. *Cavernous sinus thrombosis secondary to acute suppurative middle-ear disease.*—It has been already mentioned that infective thrombosis secondary to middle-ear disease is usually a complication of old-standing trouble and that it usually attacks the sigmoid sinus, but exceptions to this rule are occasionally found. In the following case the thrombosis supervened upon an acute attack of suppurative middle-ear disease, and involved the cavernous sinus, with the formation of an acute pyæmic abscess in the retro-ocular connective tissue. Late upon the

FIG. 2.

adopt was to tie the internal jugular vein in the neck, to expose the lateral sinus, open it, and clear out the thrombus which from the previously detailed symptoms was supposed to be present. The patient was accordingly put under an anæsthetic, and an incision was made from a point half an inch behind the attachment of the external ear down over the mastoid process to a point upon a level with the lower border of the thyroid cartilage. Very considerable difficulty was experienced in finding the internal jugular vein owing to the swollen and matted condition of the cervical structures; and as the anæsthetic was being badly borne it was decided to postpone the operation, and to try by freely stimulating the patient to arouse his vitality. Beef-tea, brandy, milk, eggs, and quinine were freely administered. During the two following days the patient had several rigors. He partook freely of nourishment and apparently gained strength. On the 24th he was again put under an anæsthetic and the operation resumed. The incision in the neck was prolonged for another inch and a half, and a careful dissection made until the carotid sheath was reached. This was immediately opened, and two ligatures were placed round the vein at a distance of half an inch from one another. The vein was then divided between the ligatures. Above the upper ligature the vein was felt to be tense as if it contained some firm substance. A three-quarter-inch trephine was now applied immediately over the region of the lateral sinus and a disc of bone removed. The opening thus made was enlarged by means of gouge and bone forceps until one inch of the vertical portion of the sinus was exposed. The sinus felt firm to the touch and no pulsation was visible. A longitudinal slit was now made through the outer wall of the sinus. Very little blood escaped. A

evening of Sunday, July 16th, 1893, I was summoned to the country to see a child who was suffering severely from the effects of acute suppuration of the middle ear. The patient, a girl aged nine years, had complained during the preceding fortnight of pain in the right ear, accompanied by a profuse purulent discharge. The ear trouble was considered secondary to an attack of sore-throat, which in turn was suspected by the medical attendant (Dr. Whitaker) to have been of scarlatinal origin, a case of scarlet fever existing in the house at the time. During the day preceding my visit intense pain over the right mastoid process had been complained of. The previous history of the patient had been good, and never at any time had there been evidence of ear trouble. Upon examination the right external meatus was found full of pus. After syringing, a small pulsating perforation was seen in the posterior inferior segment of the membrana tympani. The superior posterior meatal wall close to the attachment of the membrana tympani was found prolapsed. The tissues over the right mastoid process were slightly infiltrated and cedematous. The slightest pressure over the region of the mastoid antrum produced pain, and even gentle percussion made the child shriek. The temperature was 105° F., the pulse 120, the tongue furred, and the surface of the body dry and burning. Great headache was complained of, and the child lay coiled up in bed with her hands tightly clasped over the forehead, which position she said eased the intense suffering. The opinion arrived at was that acute empyema of the mastoid antrum secondary to acute suppurative middle ear disease existed, and an immediate operation was advised. With the assistance of Dr. Whitaker the operation was begun at 1 A.M. on

Monday. The mastoid antrum was opened in the usual way, and was found to contain a small quantity of thick creamy pus. The perforation in the membrana tympani was freely enlarged, and a warm 1 in 2000 bichloride solution syringed from the antrum through the middle and external ears. A drainage-tube was now inserted into the antral cavity, the parts dusted with iodoform powder, and the usual dressings applied. At 8 A.M. the same morning the patient's condition was found to be much more satisfactory. The temperature had fallen to 97.4°, and the pulse to 86. The pain had also become much relieved, and the child was able to partake freely of nourishment. During the day, however, the temperature began to rise again, and by 4 P.M., when the wound was dressed, the temperature had reached 100°. The following day, July 19th, the patient had a severe rigor, the temperature reaching 103.5°. Profuse diarrhoea of an extremely offensive character accompanied this rigor. Severe pain over the abdomen was complained of, and copious vomiting followed. A dose of calomel was given and the body was sponged with tepid water, while hot fomentations were applied over the surface of the abdomen. Hot boracic fomentations were also applied to the ear. Free discharge of pus followed. The same evening at 10 P.M. the temperature reached 105°, but no rigor was observed, although the child complained of feeling very cold. A consultation now took place between Dr. Whitaker, Dr. Gillibrand, and myself, and the opinion arrived at was that thrombosis of one or other of the adjoining intracranial sinuses existed, and further operative interference was advised. The idea was to expose the sigmoid sinus, to thrust a hypodermic needle into it, and if found thrombosed to open and clear out the thrombus while at the same time ligaturing the internal jugular vein. The guardians of the child, however, absolutely refused to allow anything further to be done. During the following three days the condition was shortly as follows. On July 20th she had a rigor at 8 A.M. The temperature was 104° and the pulse 114. Cold pack was employed and effervescent antipyrin given internally. She had a rigor again at 4 P.M. The temperature was 105.8° and the pulse 145. Intense pain was complained of in the abdomen, slightly relieved by hot fomentations. The stools were very offensive. On July 21st she had a rigor at 4 A.M. The temperature was 103.6°; during the day she complained of pain referred to the back of the right eyeball. The pupils were equal and reacted to light. There was no optic neuritis. She had another rigor at 10 P.M. The temperature was 104.6° and the pulse 132. On July 22nd her general condition was somewhat better. There were no rigors. The temperature at 4 P.M. was 101° and the pulse 120. She was taking nourishment and stimulants freely. Slight oedema of the right upper eyelid was noticed, and slight blurring of the right optic disc. The ear was discharging freely. There was no special pain about the mastoid region, and no puffiness along the course of the internal jugular vein. On July 23rd the patient had a rigor at 2 A.M. The temperature was 104.4° and the pulse 124. During the day the oedema of the right upper eyelid became more marked. Intense optic neuritis was present, and excruciating pain was complained of behind the right eyeball, which was now protruding from the socket. On July 24th the pain behind the eye was very severe, the right upper eyelid was very oedematous, and there was marked protrusion of the eyeball. The temperature at 6 A.M. was 103° and the pulse 130. At 9 A.M. the right eyeball was excised by Dr. Gillibrand. The orbital cavity was found full of foul-smelling pus. At 12 P.M. upon the same day the temperature was 104.2° and the pulse 126. The stools were dark in colour and offensive. During the rest of the day her condition was much more comfortable. On July 25th the temperature at 8 A.M. was 100.2° and the pulse 102. Boracic fomentations were applied to the eye and ear. Towards evening great pain was complained of in the head and throat. She had a rigor at 6 P.M. The temperature was 104.2°. On July 26th the temperature fluctuated very considerably. Her general condition was better on the whole. She had a slight headache. The stools were still very offensive. On July 27th the temperature had been gradually falling. Her general condition was much better. She slept well and took considerable quantities of nourishment and of stimulants. From this time the patient gradually improved, and in a few weeks' time appeared perfectly well. Nine months afterwards I had an opportunity of again examining the child, when the following note was made: "Her general condition excellent; perforation of right membrana tympani healed; cicatrix hardly visible. Hearing power: right side $\frac{1}{2}$ of the normal.

Mastoid wound completely healed, good linear scar." The above case is of peculiar interest as it affords an illustration of thrombosis following an attack of acute suppurative middle-ear disease and also of implication of the cavernous sinus followed by purulent thrombosis of the ophthalmic veins and retro-ocular abscess. Whether the cavernous sinus was implicated as the result of an extension of the thrombotic process from the superior petrosal sinus, or whether the sigmoid sinus was the one primarily affected and extension to the cavernous sinus took place secondarily must remain matter for conjecture.

Manchester.

STERILISATION OF MILK.

By ALFRED H. CARTER, M.D., F.R.C.P. LOND.,

SENIOR PHYSICIAN, QUEEN'S HOSPITAL; PROFESSOR OF THERAPEUTICS, MASON COLLEGE, BIRMINGHAM.

STERILISATION of milk which is intended for the food of infants or invalids cannot be dismissed as a mere antiseptic fad, for it derives its sanction from no less an authority than nature herself. The milk of all healthy animals is sterile at the time of its secretion and discharge, and under natural conditions it is derived in this state direct from the breast. It does not long remain sterile. From the moment it is exposed to the air it becomes contaminated with various micro-organisms, both fermentative and saprophytic, and occasionally with those of a pathogenic nature. On their introduction into the body they cause little or no inconvenience as a rule, owing to the fact that in the healthy alimentary canal most of them are either destroyed or exposed to conditions unfavourable to their further growth and development; but in unhealthy states it is far otherwise. Fermentative processes are then apt to occur which set up more or less active irritation and inflammation, and in the presence of pathogenic organisms specific disease may follow in susceptible persons. Sterilisation aims at preventing these risks by the destruction of micro-organisms in milk. In other words, the intention is to bring back the milk to the state in which nature originally supplied it. When it is possible to get milk in a perfectly fresh state sterilisation is of course unnecessary, and the same is true for all practical purposes when milk is only kept for a short time under favourable conditions of temperature and cleanliness; but the conditions of milk-supply in large towns, and particularly to the poor in summer time, are such that it is scarcely possible to obtain it free from bacterial contamination of a serious kind without special precautions. It is under circumstances of this kind that the principle of sterilisation may be beneficially applied. By merely bringing milk to the boiling point for a few minutes the majority of micro-organisms may be destroyed; but it requires prolonged exposure to a considerably higher temperature in order to secure complete sterilisation. For practical purposes, however, complete sterilisation is unnecessary. It must be borne in mind that boiled milk undergoes fermentative change almost as quickly as raw milk on free exposure to the air, so that in order to secure the advantages of boiling milk it must either be consumed soon afterwards or subsequent contamination must be prevented. The latter can readily be effected by boiling in bottles (soda-water bottles by preference) the mouths of which are plugged with cotton-wool. The plugs should of course remain *in situ* until the moment that the contents are required for use. This simple method of sterilisation carries with it a very considerable advantage, and if it were uniformly practised in preparing food in hot weather there is no doubt that diarrhoeal affections would be far less frequent than they are. A great variety of apparatus has been devised on this principle, but so far as I am aware they offer no decided advantage to the small consumer over ordinary boiling, which can be carried out in every household, however humble.

It would seem *prima facie* that there was little more to be said on the subject; but it is a matter of general experience that while milk sterilised by boiling is most valuable in the prevention and treatment of gastro-intestinal disorders, not only in infants but in adults, yet as a permanent food it does not fulfil the requirements of perfect nutrition. For a permanent food it is essential that it should possess the element of freshness, or at least contain a due proportion of

some fresh ingredient, in the absence of which scorbutic troubles are apt to arise. Now there are strong reasons for believing that boiling does to a large extent devitalise milk and deprive it of its fresh properties. As to what these properties really are, we have no precise knowledge. That this devitalisation is something more than a mere figure of speech is demonstrated by the fact that perfectly fresh milk has a bactericidal action, like fresh blood, which gradually passes off as the milk loses its freshness. It has been shown that this effect is abruptly destroyed by raising milk to the boiling point. Interesting as this matter is, there is no occasion for my present purpose to dwell upon it further. Again, all the best observers agree in asserting that boiled milk is somewhat less digestible than raw milk, a result which must be attributable to some chemical change or changes induced by boiling. Thus, according to Leeds¹ and Koplik² other changes are determined by boiling. It coagulates the lactalbumen; it separates out some of the fat, so that it runs together to form little spots of pure butter; it breaks up the milk-sugar more or less completely; and the casein is coagulated by rennet with greater difficulty. The question then arises as to whether it is possible to destroy the organisms which milk contains without rendering it less digestible. Pasteur has shown that exposure of milk for a short time to a temperature of 131° F. is sufficient to prevent its turning sour, while Koch, Klein, and many others have proved a temperature of 151° to 158° maintained for five minutes is sufficient to destroy all non-sporebearing organisms. Now, so far as can be ascertained, the chemical composition of milk is not seriously disturbed by temperature of this grade, while ordinary fermentative and putrefactive changes are indefinitely postponed or altogether prevented. In order to distinguish this method of treating milk from that by boiling it has been called "pasteurisation." For the purpose of preventing the growth and development of bacterial spores which still retain their vitality it is most desirable that the milk should be quickly cooled as soon as the process of pasteurisation has been completed. Pasteurised milk has been largely used by Freeman, Waldstein, and others in America, who report excellent results. There are some differences in the length of time for which the pasteurising process is continued in the practice of different physicians, varying from twenty minutes to an hour and a half. Dr. Waldstein has invented a most simple and ingenious apparatus for pasteurising milk, which has been submitted to me for trial and an opinion of its merits. I may describe it in his own words:—"I have

composed of three separate divisions, soldered together in such a manner that it is practically of one piece. Between the inner and outer chamber an air-space of one-sixteenth of an inch is interposed, from which the heated air escapes by holes punched in the top. When it is to be used both compartments are filled with boiling water, the rack containing the bottles is submerged into the inner one up to the milk-line, then covered over with the lid, and allowed to remain upon the stove during an hour and a half. The milk in my apparatus never reaches a higher temperature than 72° C. (160° F.), never one below 70° C. (158° F.); the water around the bottles is soon reduced to and remains at 75° C. (167° F.) or a little over, and the water in the outer compartment is kept boiling during the entire time." It should be pointed out that in order to prevent undue separation of fat, and also with a view of reducing the risk of subsequent bacterial development to a minimum, it is essential that the milk should be quickly cooled at the conclusion of the process. This can readily be done by removing the rack with its bottles from the tin, and plunging it into cold water and keeping it there. I had a good deal of difficulty at first in the breakage of bottles caused by this proceeding; but with a better class of bottles than those supplied with the apparatus these accidents seldom occur. During the last six months the apparatus has been in use at the City Infirmary and the Queen's Hospital, and has given considerable satisfaction. It is easy to use, children and other patients for whom it has been employed like it, and in no single instance has it been found to disagree. It appears to be more readily digested than raw milk, and several instances have come under my notice in which it has agreed when raw milk has disagreed. This may be partly due to the fact that the curd on coagulation is looser and more flaky than is the case with ordinary milk, but it is probably due chiefly to the much less liability to undergo acid fermentation. I have had some few complaints of constipation among young children, but in some of these it was unquestionably due to lime-water which had been added to the milk, and in no case was it troublesome. I have also used it in a case of ulcer of the stomach and in two cases of typhoid fever, and in all three it answered very well. I am wishing to try it in some of those cases in which there is a stubborn idiosyncrasy against milk, occurring generally in gouty subjects with a tendency to acid dyspepsia, but as yet I have had no opportunity of doing so. Dr. Waldstein says, however, that in these cases he has never failed with the addition of a teaspoonful of a $\frac{1}{2}$ per cent. solution of hydrochloric acid to each cupful of milk. In further support of what I have said I will turn to a brief series of consecutive cases, kindly reported for me by my colleague, Dr. Short.

CASE 1.—A man aged fifty-six years had chronic gastritis and pain after all food, especially milk. He was ordered pasteurised milk. For the next five days he gradually improved, and there has been no recurrence of the pain.

CASE 2.—An infant aged twenty-one months had otorrhoea, foul stools, and diarrhoea at intervals. Milk and lime-water had been administered without relief. Pasteurised milk was then ordered. In seven days the character of the stools had greatly improved; there were only two daily movements, as against four and five previously. This treatment was continued for a month, and the patient then returned to his ordinary diet. There has been no return of the diarrhoea.

CASE 3.—A man aged twenty-nine years had extensive phthisis. He had vomited every morning for three weeks, in spite of changing his breakfast hour. Pasteurised milk was ordered. For twelve days he did not vomit, and he then returned to his ordinary diet. The patient has not vomited since.

CASE 4.—The patient was a female infant aged nine weeks, a twin child, very small and ill nourished, suffering from diarrhoea and vomiting. She was put on pasteurised milk, with lime-water and cinnamon water. The sickness stopped, but the bowels still remained loose and death ensued a month later.

CASE 5.—A female infant aged one year had diarrhoea and vomiting. For three weeks she had ordinary milk and lime-water without relief. She was then put on pasteurised milk, three parts milk and one part water. She gradually improved and gained a little flesh. The diarrhoea ceased, and vomiting was seldom.

CASE 6.—The patient was a man with gastro-ectasis following ulceration, with frequent vomiting. In this case the vomiting was not affected by the pasteurised milk unless the stomach was washed out once a week.

made use of a patented idea of my brother, Dr. M. E. Waldstein, in constructing this apparatus. The principle underlying it is very simple. It turns upon the reduction and equal maintenance of the temperature of the water in an inner compartment, B, separated from an outer one, A, in which the water is kept boiling, by an air-space, C, which is larger or smaller according to the difference of temperature which it is desired to obtain. The apparatus is made of tin and is

¹ American Journal of the Medical Sciences, June, 1891.

² Archives of Pediatrics, June, 1891.

In conclusion, I will quote the Sister of one of the children's wards in the City Infirmary, who has used pasteurised milk as a routine food for many of the children under her charge. She says that it has answered better for all-round use than any artificial food she has tried, that it is especially useful in cases of chronic diarrhoea, and that for green offensive stools it seems to be a certain remedy. I venture to submit that with this evidence before us pasteurisation of milk is worthy of our attention, and that Waldstein's apparatus is a cheap, simple, and effective method of carrying it out in practice. The apparatus can be obtained from Messrs. Philip Harris & Co., Limited, Birmingham, at a cost of 12s. 6d.

Birmingham.

CASE OF MOLLUSCUM FIBROSUM.

By F. K. GREEN, F.R.C.S. ENG.,

SURGEON TO THE BATH ROYAL MINERAL WATER HOSPITAL; ASSISTANT SURGEON TO THE ROYAL UNITED HOSPITAL, BATH.

THE following case of molluscum fibrosum may be considered interesting on account of the large size, peculiar appearance, and situation of one of the mollusc growths.

A man sixty-one years of age was admitted into the Bath Royal United Hospital on Dec. 12th, 1890, under my care, during the absence of my senior, Mr. Fowler. The patient was a man of stunted growth and dull and feeble intellect. He was dark-complexioned and, with the exception of the face, his skin was thickly freckled; in some places the skin was pigmented over an area the size of a sixpenny piece. The most striking feature about him was the peculiar hypertrophy of the skin and subcutaneous tissue of the left side of the face, which caused it to hang in folds, resembling somewhat the face of a bloodhound. These folds of skin hung down two inches below the level of the jaw. They felt quite soft and evidently contained nothing but loose connective tissue and a little fat. The patient said that his mother had

told him that his face had always been more or less in this state, and that when born there was an excrescence the size of a horse bean on that side; also that the deformity had been much more marked, the hanging folds of skin being larger than at present. On the trunk and limbs were innumerable warty growths and subcutaneous tumours, mostly of very small size. The warty growths were both sessile and pedunculated, and most abundant on the trunk, the subcutaneous tumours being almost entirely distributed over the limbs, and of variable size. The largest of these tumours was a sessile one in the episternal notch. It was roughly oval in shape and about an inch and a quarter in length, very soft, and much puckered on the surface. The next in point of size was situated on the scalp in the left parietal region and was of irregular shape. About two inches below the right nipple was a pedunculated tumour as large as a bean; two upon the right buttock had bases larger than a shilling and stood out prominently beneath the skin. They were all soft to the feel. The patient was admitted on account of a large endosteal sarcoma involving the whole of the left forearm, which I amputated soon after admission. The

stump healed quickly, but a cough developed, and symptoms of sarcoma of the lung appearing he was transferred to the medical side of the hospital, where in a few weeks he died.

Necropsy.—This revealed extensive sarcoma of the lungs, which under microscopic examination showed large spindle cells. A peculiar feature in this case was the extensive freckling or pigmentation over the body. Curiously enough in looking through an odd volume of the Irish Medical Transactions for the year 1828 I found a similar case recorded by Dr. John Crampton, with an excellent engraving of the patient. The noteworthy features in the case were the large size of the mollusc growths and "large freckles and dark-brown olive spots of various shape and size occupying the cuticle in patches." It would be interesting to know if the coexistence of molluscum fibrosum and pigmentation has been noticed by dermatologists. Perhaps it is only coincidence. Dr. Liveing has pointed out that "it is highly probable that these outgrowths exist in an undeveloped form at the time of birth, though they may be too small to be detected." In the case I have narrated it would certainly appear from the mother's statements that the growth on the face was well developed at birth. The stunted body and feeble intellect of the patient were especially marked, and support the observation of Hebra that molluscum fibrosum occurs very often in people with mind and body imperfectly developed.

Bath.

TWO CASES OF SYPHILIS WITH EARLY NERVOUS MANIFESTATION.

By HENRY LEE, F.R.C.S. ENG.,

CONSULTING SURGEON, ST. GEORGE'S HOSPITAL AND QUEEN CHARLOTTE'S Lying-IN HOSPITAL;

AND

J. A. SHAW-MACKENZIE, M.B. LOND., M.R.C.S. ENG.

As bearing on the late discussion initiated by Mr. Hutchinson at the Royal Medical and Chirurgical Society, Dr. Shaw-Mackenzie has Mr. Henry Lee's kind permission to forward the only two cases he can find of early nervous manifestations, out of 2750 cases of syphilis in some of Mr. Lee's case-books. Whether they are true secondary lesions is apparently uncertain. That they followed primary syphilis within two years is undoubted.

No.	Sex.	Age.	Primary.	Date of secondary nervous affection.	Description of manifestation.
1	F.	14	Sore on labium noticed for two months the size of a shilling piece.	Two months.	Dyspnoea; tracheotomy; convulsive movements of limbs; partial coma for a week; sphincters relaxed; death. Necropsy.—Dura mater adherent, thick and red in patches; brain congested; ventricular walls soft, with fluid effusion; tonsils puckered and purulent; very large quantity of mucus fills larynx and pharynx.
2	M.	32	History of syphilis, vide Mr. Lee's "Lectures on Syphilis"	Eighteen months.	Loss of power right side of body, with difficulty in speech; at 23 months facial paralysis of left side, ptosis of left eyelid, and right arm powerless; death. Necropsy.—Dura mater has partly fibroid, partly caseating, and degenerating tumours, varying in size to a florin piece; similar masses were found in the Sylvian fissures; left optic nerve atrophied from pressure of growths. Microscopic examination by Dr. Whipple showed spindled nuclei in fibrillated network; the softer parts showed degenerated cells and broken-down fibrous tissue. No fibrillation was evident in the earlier growths; the liver substance was studded with transparent nodules of newly formed fibrous tissue.

The following cases of patients presenting themselves with late nervous manifestations are taken from the same source:—

No.	Sex.	Age.	Primary and secondary.	Date of primary nervous affection.	Early treatment.	Late nervous manifestation not secondary to bone lesion.
1	M.	37	Sore papular eruption; ulcerated throat.	16 years	Pills, 2-3 years	Loss of smell and taste.
2	M.	—	History of syphilis.	30 years	?	Loss of smell and taste.
3	M.	—	"	6 years	Pills of red iodide, 6 weeks.	Loss of sexual power; tremors; aphasia; unsteady gait; difficulty in swallowing; death.
4	M.	—	"	16 years	At Aix twice.	Impotence; advancing melancholia; suicide, though under care of trained male attendant.
5	M.	—	"	10 years	(?)	Impotence; mental depression.
6	M.	40	"	16 years	Pills	Patches of numbness in anterior thighs, also in fingers; variable superficial cutting pains; tremors; knee-jerks deficient; mental depression.
7	M.	50	"	20 years	Mixed	Locomotor ataxy affecting sensory roots.
8	M.	40	"	5 years	Baths	Vague persistent headache, dimness of sight, reduced sexual power.
9	M.	—	"	2-3 years	Baths	Vague headaches and dizziness.
10	M.	—	"	30 years	(?)	Slight hemiplegia; died a year later of apoplexy.
11	M.	60	"	18 years	Pills, 2 years	Malnutrition; mental depression; deficient sexual power; neurasthenia.
12	M.	40	Hard sore	17 years	Baths	Deafness; loss of energy; noises in head.
13	M.	—	History of syphilis	3 years	Baths	Ringings in ears.
14	M.	—	"	—	—	—

Mr. Lee's case-books show further cases in the later stages of syphilis of neuralgia of the nerves of the back, sciaticas, debility, rheumatic pains, muscular twitchings, slight losses of muscular power, numbness and deafness, loss of smell, delusions, three to twenty years after primary history, whilst particulars of eleven other cases are found in his lectures on Syphilis. Mr. Lee has met with but comparatively few affections of the nervous system as the result of syphilis, and these he can account for by want of care in the primary stages. He considers it essential in the treatment of early syphilis that exposure to air should be avoided as much as possible, and he cannot remember a single case of gross lesion of the nervous system or internal organs following the careful and detailed primary use of the calomel fumigation bath. In a paper by Dr. Shaw-Mackenzie¹ he stated that many cases of late syphilis which had been treated by mercury internally in the primary stage or irregularly seemed to be intolerant to the further beneficial effects of mercury; also that he had been struck by the few manifestations of syphilis in patients who had been treated from two to thirty years previously for primary syphilis by the calomel bath. He would submit that a method which makes the least demand on a patient's constitution, which does not conduce to digestive troubles and malnutrition, may also, in aiding elimination through the skin, prove truly prophylactic against the later manifestations of syphilis.

Savile-row, W.

¹ THE LANCET, May 6th, 1893.

A CASE OF IDIOPATHIC RUPTURE OF THE HEART.

By DUDLEY W. COLLINGS, M.B.,
SENIOR HOUSE SURGEON, TOTTENHAM HOSPITAL.

A MAN, aged fifty-three years, was admitted into Tottenham Hospital on Aug. 7th, 1894, with the following history. He had lived a temperate, sedentary life, being troubled only by dyspepsia and a weak heart. He denied ever having suffered from rheumatism or rheumatic fever. His father died suddenly of heart disease. He had been in his usual state of health and at work up till Aug. 1st, 1894, on which date he felt "out of sorts." On the 2nd he experienced severe pain in the præcordium, and felt too ill to leave

Anterior view of heart and bases of lungs. A small piece of wood is inserted in the rupture. The upper wound, in the left auricle, was made during the necropsy.

his bed. On the 3rd he was worse and sick after food. On the 5th, about midday, his speech became rather thick, but recovered its natural tone later on. At tea-time his mouth was noticed to be drawn to the right side and his left eye was partially closed. The left arm became paralysed, followed by loss of motion in the left leg. On his admission on the 7th he was found to be well nourished, but looked old for his years. He answered questions clearly and explicitly, though with some slight hesitation. The left side of his face (lower part), left arm, and left leg were paralysed. The tongue was deviated to the right on protrusion. The sphincters were unaffected. There was no pain. The heart sounds were faint and there were no added sounds. At about 11 A.M. on Aug. 8th he was moved on to a water-bed, his body and head being kept horizontal, great care being taken to avoid any sudden

movement. At 6 15 P.M. his pelvis was raised to allow of the introduction of a bed-pan and almost instantaneous death ensued. At the post-mortem examination a prolonged and careful search failed to reveal any macroscopic change in the brain, its vessels, or the meninges. On opening the pericardium it was found to be filled with blood clot, and on washing this away a laceration about one and a half inches in length was found in the left lateral wall of the left ventricle. The aperture was closed by recent clot. The cavities of the heart were dilated, the walls thin and in an advanced stage of fatty degeneration. No valvular disease was present. The aorta and its main branches were atheromatous. Both lungs contained calcifying tubercle; the abdomen was loaded with fat; the spleen was soft and friable; the kidneys were engorged, but otherwise healthy. Although the patient's death followed such a slight movement as that of raising his buttocks, and which was apparently "the last straw," he had been able to survive a considerable journey (from Waltham Abbey to Tottenham) in a cab on the previous day. My cordial thanks are due to Dr. Rasch, visiting physician to the hospital, for his permission to publish this interesting case.

TWO CASES OF DIPHTHERIA TREATED BY ANTITOXIN.¹

By A. J. RICHARDSON, M.A., M.D. CANTAB.,
ASSISTANT PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL.

CASE 1.—The patient was a girl aged seven years and six months. On Sept. 11th she was said to have had tonsillitis, but to have completely recovered by the 15th. On the evening of Sept. 20th there was copious epistaxis. On the 21st, on the right side of the uvula and anterior pillar of the fauces, there was a shallow, raw-looking ulcer, and the left nostril was filled with a greyish-white membrane down to the orifice. The pulse was 130 and the temperature 101° F. The urine contained over 0.05 per cent. albumen. The patient was given perchloride of mercury and lactic acid (one drachm to the ounce) applied locally. On the 22nd with a nasal speculum a white substance could be seen far back in the right nostril. On the 23rd the temperature reached 102° 2', and the child was distinctly worse. On the 24th the urine contained over 0.03 per cent. albumen. At 7 P.M. 0.7 c.c. of Aronson's antitoxin was injected. On the 25th the patient could breathe better through the nose. She was very restless in the afternoon and her temperature rose to 103°. On the 26th the ulcer on the uvula was nearly well. No membrane could be seen in the nose, but the temperature was still keeping over 102° and the albumen had increased to 0.2 per cent.; 1.2 c.c. of antitoxin injected. On the 17th she complained of pain in the legs, and after the most careful examination the knee-jerks could be only doubtfully obtained; anyway, there was very slight reaction. The fauces and nose looked well, but she complained of ear pain. On the 28th pus issued from the right ear. The patient could not hear the ticking of a watch on contact, and the tympanum was perforated. On the 30th the ear was quite free from discharge, and she heard a watch at three inches. The throat and nose looked well, but the temperature reached 103° 2', and the albumen was over 0.1 per cent.; 1.7 c.c. of antitoxin was injected. On Oct. 2nd the temperature was subnormal and the pulse 92. Albumen, 0.01 per cent. On the 3rd the temperature was subnormal, the pulse 104, and there was no albumen. The knee-jerks were very glib. Since then the child has made an uninterrupted recovery.

CASE 2.—The patient was a woman, the mother of the above. On Sept. 23rd a small yellowish patch was seen between the pillars of the left fauces. The temperature was 103° F. Steam and lactic acid were applied locally, and perchloride of mercury given. On the 24th albumen was 0.1 per cent. The yellow patch had grown a little. There was a separate raised white patch between the uvula and the anterior pillar. In the evening a third patch had appeared on the left tonsil. The temperature was 100° 2'. 1 c.c. of antitoxin was injected. On the 25th, in the morning, the yellow patch had come round the anterior pillar and spread

downwards. The white patch and the third patch remained as on the previous day. In the evening the yellow patch had receded; the edges of the white patch were raised and everted, while the third patch remained as before. On the 26th the yellow patch and the third patch were smaller; the white patch of membrane shed. The temperature was 99° 2'. On the 28th the throat was absolutely clear. The temperature was normal and the urine free from albumen. The patient has since progressed without any bad symptoms.

Remarks.—The cases were not in any sense treated with a view of determining the merits of antitoxin; still, the circumstance that both failed in any way to improve until the antitoxin was injected is noteworthy. The mother received her dose on the second day of the disease, and the child much later, so the cases bear out what has been written—that the sooner antitoxin is administered the better is the recovery, and that the later in the disease the larger is the dose required to produce benefit. The estimations of albumen were by Brandenburg's method (checked by Esbach's tubes), but only on particular samples, not on the mixed urine of twenty-four hours. The disease is attributed to an arrangement by which a current of air was allowed to pass through the dustbin into the house.

Hove, Brighton.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PREGNANCY IN ONE HALF OF A UTERUS SEPTUS BICORNIS.

By E. G. EMERSON ARNOLD, L.R.C.P. LOND., M.R.C.S. ENG.,
SENIOR OBSTETRIC HOUSE PHYSICIAN TO ST. THOMAS'S HOSPITAL;

AND

W. E. F. TINLEY, M.B., B.S. DURH.,
JUNIOR OBSTETRIC HOUSE PHYSICIAN TO ST. THOMAS'S HOSPITAL.

A WOMAN aged twenty-two years was attended in the Maternity Charity of St. Thomas's Hospital on Feb. 4th, 1895, in her third confinement. On examination the left shoulder was found presenting with the arm prolapsed. The patient had been in labour for upwards of twelve hours, and the os was fully dilated. On passing the hand into the uterus in order to perform version, after the patient had been put under chloroform, there was felt, close against the uterine wall and just above the child's head, which was lying in the left iliac fossa, a thick projecting edge of tissue, the nature of which was not at the time apparent. Delivery was effected by version, the child, a full term male, being stillborn. On examining after delivery it was found that the uterus consisted of two distinct cavities, divided by a septum reaching as far as the position of the internal os, and the fundus presented a median depression separating two divergent cornua. The placenta and membranes were found occupying the right and larger half of the uterus, the left side being empty, but lined by a soft membrane, easily breaking down under the finger. It was now obvious that the projecting edge previously felt had been the lower end of the septum pressed against the left uterine wall. The placenta and membranes were expressed without difficulty, and, some hæmorrhage occurring, a hypodermic injection of ergotinine was administered, after which the uterus contracted well. The patient made satisfactory progress until the tenth day, when a rise of temperature occurred. An intra-uterine douche was given and a large quantity of shreds of decidua tissue evacuated from the left cavity, and these continued to pass for some days afterwards. The temperature gradually fell again to normal, and there were no further untoward symptoms. Abdominal palpation immediately after delivery showed the right half of the uterus to be markedly larger than the left, but a day or two later the left half appeared to be slightly the larger of the two. At the end of a week or ten days both sides felt of equal size. The patient has had two previous pregnancies, the first resulting in the birth of a living child at term, and the second in a miscarriage at the sixth

¹ Notes on these cases were read at the meeting of the Brighton and Sussex Medico-Chirurgical Society, Oct. 6th, 1894.

month. No interference was necessary, and nothing occurred to lead to the diagnosis of the abnormality on either of these occasions. The patient first menstruated at the age of thirteen years, and the catamenia have always been regular and rather profuse. All three pregnancies have been attended throughout by complete amenorrhœa. The pelvis showed no increase in width, such as has been noticed in some cases of double uterus. The promontory of the sacrum was somewhat prominent, and there was some contraction of the conjugate diameter of the brim, without, however, those changes in the external measurements characteristic of the rachitic flattened pelvis. The measurements were: diagonal conjugate, 4½ inches; distance of iliac crests, 10½ inches; distance of iliac spines, 9½ inches. Our best thanks are due to Dr. Cullingworth and Dr. Cory for permission to publish this case.

REMARKABLE CASE OF PERFORATION OF EYEBALL.

By H. A. BRYANT, M.R.C.S. ENG. &c.,

RESIDENT MEDICAL OFFICER, COUNTY HOSPITAL, DURHAM.

ON April 3rd a man twenty-one years of age attended the Durham County Hospital with the history that, while walking beside his cart with a friend, he was suddenly struck with something in the right eye, causing him intense pain and loss of sight. On examining him I found a lacerated perforating wound the size of a hemp seed about three-sixteenths of an inch from the outer margin of the cornea, out of which some of the vitreous was escaping. The conjunctiva was congested, there were blood in the lower half of the anterior chamber, but not blocking up the pupil, loss of tension, and sinking in of the iris and lens. Loss of sight both for light and objects was complete. Ophthalmoscopic examination could detect nothing, no reflex being present, and no foreign body could be seen with focal illumination. About four hours after the accident the man was put under chloroform, and I passed a probe into the wound for about an inch in a downward, backward, and inward direction, encountering what seemed to me to be some soft foreign body. As it could not be removed the eyeball was enucleated. On examining the eye afterwards, embedded in the back part of the vitreous a knot of whipcord, evidently from the end of a whip, was found, which must have penetrated the globe and passed through the vitreous. The lens was uninjured. The patient made a good recovery, and left the hospital seven days after the operation. On questioning him he was quite at a loss as to how the accident could have occurred, declaring that his own whip was in the cart, and that no one anywhere near was flicking one about. The case is that of an accident which almost everyone is liable to, and it shows what considerable force there is in a flick of a whip which can penetrate such a tough body as an eyeball.

DISLOCATION OF THE LOWER JAW DURING AN EPILEPTIC FIT.

By CECIL F. BEADLES, M.R.C.S. ENG., L.R.C.P. LOND.,

ASSISTANT MEDICAL OFFICER, LONDON COUNTY ASYLUM, COLNEY HATCH.

A CASE of dislocation of the lower jaw during an epileptic fit is such a rare event that the following is worthy of being recorded. It occurred in a youth aged twenty who had been an inmate of Colney Hatch Asylum about two years and a half. He is the subject of chronic mania, with delusions, is often excited and quarrelsome, and has frequent epileptic fits, occurring more especially during the night, but which interfere but little with his employment on the grounds during the day. He has a somewhat imbecile expression, with a peculiar, hesitating, slow manner of speech; moreover, his lower jaw has the appearance of being rather loosely articulated. Dislocation of the right condyle occurred during the night while the patient was in a severe fit, and its reduction was effected without difficulty when he recovered from it. I have been unable to discover that this rare event has previously happened in this asylum, although some years ago there were two male patients who could put their jaws out and replace them with ease; neither of these was epileptic. Erichsen does not mention epileptic fits as a cause of this variety of dislocation.

HOSPITAL PRACTICE BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ROYAL BERKSHIRE HOSPITAL.

CASE OF DOUBLE BASIL PNEUMONIA ASSOCIATED WITH PREGNANCY, HEART DISEASE, AND BRONCHITIS, AND FOLLOWED BY EMPYEMA; RESECTION OF RIBS; RECOVERY; REMARKS.

(Under the care of Dr. FRANCIS HAWKINS.)

THERE is no doubt that pneumonia is one of the most serious complications of pregnancy, and although several cases are on record where the patient has recovered, its onset is rightly regarded with great anxiety by the physician. Dr. Rendu¹ has in a clinical lecture devoted to this subject entered fully into a consideration of it. That the disease is aggravated by pregnancy is proved by statistics, which show a mortality of 8 to 9 per cent. He further states that the more advanced the pregnancy the graver the pneumonia, the cause of this being partly mechanical, from diminution of hæmatisation; but, in addition, the heart at this period is already fatigued, and the kidneys to a certain extent altered by pregnancy, thus bringing about a serious pathological condition. The frequency of abortion, which aggravates the situation, appears to be due to the fact that the foetus dies from infection, and the uterus hastens to free itself. Dr. Rendu considers that abortion renders the patient's state more serious, and that dangerous symptoms are apt to develop very rapidly after it. This case, it will be noted, was apparently less fitted than usual to cope with the disease on account of the cardiac affection.

A woman aged thirty-five years was admitted to the Royal Berkshire Hospital on April 5th, 1894, complaining of pain in the left side, cough, and slight expectoration, all of which had commenced suddenly three days before and were not preceded by shivering or vomiting. The thorax, which was well formed, moved but slightly on the left side during inspiration. The physical signs on this side were slight vocal fremitus, absolute dullness over the infra-scapular region, marked dullness over the lower part of the inter-scapular and over the whole of the infra-axillary regions, the breath sounds tubular in character over all the above regions, a small amount of fine crepitation, and a great increase of vocal resonance. On the right side there were no abnormal physical signs. The first cardiac sound was decidedly impure, but there was no absolute murmur. The temperature was 99.6° F. and the pulse 108. The patient was at about the fourth month of pregnancy. On April 7th pain was felt in the right side of the chest, which now moved less freely in respiration, and over the infra-scapular region there was dullness with tubular breathing. The highest temperature (at 3 A.M.) was 102.5°; the pulse was 128. On the 9th the general condition of the patient was very bad, the dyspnoea being very marked and the lower lip cyanosed. The signs of consolidation of both bases were still present. The highest temperature (at 3 P.M.) was 102.6°, the pulse was 132, and the respiration 55. Liquor strychniæ was given every four hours. On the 10th the dyspnoea was less and the lower lip was not cyanosed. The highest temperature (at 11 A.M.) was 100.8° and the lowest was 98.6°. The pulse was 120 and the respiration 50. On the 11th, which was the day of crisis, or ninth day of the disease, the temperature in the forenoon was 98° and the general symptoms were rather less urgent. At 10 P.M., however, there was severe dyspnoea with constant hacking cough, and the pulse rose to 130. Digitalis and ammonia were now administered. (At first the patient was ordered brandy, which she took till the 10th, when port wine was substituted.) On the 15th the patient was not so well and complained of pain in the right posterior axillary line; there

¹ Journal de Médecine et de Chirurgie Pratique, Paris, vol. i., 1893, Sajous' Annual of the Universal Medical Sciences, vol. ii., 1894, H. 13.

was, however, no evidence of pleurisy, nor was the pain relieved by leeches. On the night of the 20th she had a very severe attack of dyspnoea, accompanied by pain all over the chest. Physical examination gave no signs of any morbid condition other than general bronchitis with pneumonia undergoing resolution, and a dilated heart. The digitalis, which had been stopped for a time, was resumed and the patient improved. Subsequent examinations showed only dulness of the right base, with tubular breathing distinct but diminishing. On May 1st the right side of the thorax scarcely moved in respiration, vocal fremitus was absent, and the dulness was increased in area, but the breath sounds were audible; the heart was slightly outside the line of the nipple. An exploratory needle introduced in the right posterior axillary line between the sixth and seventh ribs gave exit to clear fluid; a full-sized trocar was afterwards inserted at the same point, but no fluid came. On the 8th, no further attempt to aspirate having been made, there was no movement of the right side of the thorax during respiration, vocal fremitus was absent, there was dulness posteriorly and laterally, the breath sounds were inaudible, and there was slight egophony. Over the right infra-clavicular region Skodaic resonance was well marked. The apex beat was approximately one inch and a half outside the left nipple line. Aspiration now yielded more than two pints of clear fluid. On the 15th, six weeks after the commencement of the illness and five weeks after the crisis, there was slight vaginal hæmorrhage without uterine pains. Two days later severe pains were felt in the lower part of the abdomen, and a foetus between the fourth and fifth months was expelled, together with placenta and membranes. On the 19th there was an attack of urgent dyspnoea, and the physical signs showed an accumulation of pleural fluid, which on exploratory puncture was found to be purulent. A free incision being resolved on, and the patient's condition precluding the use of any general anæsthetic, cocaine was injected at the spot indicated, ice was applied externally, and an opening was made through which a pint and a half of pus escaped. On June 9th, as the purulent discharge from the drainage-tube continued and the lung did not expand much, chloroform was administered and Mr. W. J. Maurice excised portions of the eighth and ninth ribs. A drainage-tube was inserted, and the discharge was considerable until about July 16th. On Aug. 2nd there was some general movement of the right side of the thorax, and the apex beat was inside the left nipple line. A few days later the patient went to the seaside, and on Aug. 24th the tube was discontinued. On Jan. 30th, 1895, the right side of the thorax was found to move fairly well; the percussion note was slightly impaired over the right infra-scapular region, but the breath sounds were distinct. The apex beat was now inside the nipple line, and a well-marked systolic bruit was heard. The operation wound was quite healed. In March the right lung was fully expanded, the difference on auscultation and percussion of the two sides being but small. The cardiac murmur was variable in its distinctness.

Remarks by Dr. HAWKINS.—Pneumonia when associated with pregnancy is by nearly all writers regarded as being extremely dangerous, abortion invariably taking place. I know of but one case other than that now under review where abortion occurred and recovery followed. According to several authorities, including Dr. Wilson Fox, pre-existing heart disease, from which my patient suffered, is another most serious complication of pneumonia, increasing the mortality to 30 and 50 per cent. The present case therefore seems to show that pneumonia, even under the most unfavourable circumstances, if early brought under treatment and managed with strict attention to certain practical details, is a disease which ordinarily tends towards recovery.

DONCASTER GENERAL INFIRMARY AND DISPENSARY.

ANEURYSM OF THE AORTIC ARCH IN A YOUNG WOMAN;
NECROPSY; REMARKS.

(Under the care of Dr. A. CHRISTY WILSON.)

THIS case is interesting on account of the unusual conditions alluded to by Mr. Armit in his remarks. Dr. Bristowe¹ writes on this subject: "Aneurysm is a far more common affection in males than in females, mainly on account

of their different avocations, and it belongs almost exclusively to adult life. It is a disease, indeed, chiefly of advanced years; still, it not infrequently occurs, both in men and women, between the ages of thirty and forty, and especially in those who have led debauched lives and have suffered from the conditions which produce endoarteritis." Aneurysm of the aorta has, however, been observed at a much earlier age. Dr. Penden² showed a girl aged twelve, at the St. Petersburg Medical Society, with the following signs: to the right of the sternum there was a slightly prominent dull area which pulsated; the pulse in both wrists was delayed relatively to the apex beat; a double murmur was heard loudest over this area. There were no symptoms. When six years old she had fallen and struck her right side, and since that time she had had moderate pains in that region. Mr. Edgar Willett³ brought before the Pathological Society a specimen removed from the body of a girl aged four, showing a sac, the walls of which were thick and well formed, which communicated with the descending portion of the aortic arch. He considered that it might have been produced by the breaking down of an enlarged lymphatic gland, the contents of which had passed into the aorta. The child had died from pericarditis.

A woman aged thirty-three (according to her friends) was found bleeding profusely from the mouth whilst walking in the street, and was taken to the Infirmary at noon on March 23rd, 1895. She was seen to have lost a great quantity of blood before admission, and continued to do so after. The blood was vomited as well as coughed up, and was frothy, arterial and alkaline. The quantity of blood lost was not known, owing to the fact that much had been lost in the streets, and when in the room where she was first brought the patient was extremely restless, throwing herself about, so that only a portion was collected in vessels. When first seen she was extremely pallid, with widely dilated pupils, and the radial pulse was scarcely to be felt at the wrist. She was still spitting and vomiting blood profusely. At Dr. Wilson's request (under whose care the case was admitted) Mr. Armit injected ten minims of ergotin hypodermic solution, but did not succeed in controlling the hæmorrhage to any marked extent. After about fifteen minutes she became less restless and the hæmorrhage diminished and ceased, but the patient was so collapsed that she was unable even to swallow ice or iced water. The voice was markedly changed, being of that peculiar staccato, breathless type so typical in extreme anæmia. There were dyspnoea and bubbling sounds heard by the unaided ear, indicating the presence of a considerable quantity of blood in the air vesicles. In less than three-quarters of an hour another smaller attack of hæmorrhage occurred, but subsided quickly. Mr. Armit gave orders that if she did not have a return of hæmorrhage in a couple of hours she was to be carefully moved on a stretcher into one of the wards. This was done at a little past four. At five o'clock another hæmorrhage, not very profuse this time, set in, and the patient died very soon after. Mr. Armit had thus no opportunity of examining her chest or abdomen during life, and so did not form a definite diagnosis as to the cause of the hæmorrhage. On inquiry he found that she had been ill for about two years, and had suffered chiefly from lung symptoms—i.e., cough, expectoration, dyspnoea, &c., and some laryngeal trouble, indicated by a change in the voice. He could get no definite reliable history as to the patient's previous habits, but was informed that she was not temperate. On Monday, March 25th, Mr. Armit made a post-mortem examination. She was found to be a well-nourished woman with a moderate amount of subcutaneous fat. On opening the chest the left lung seemed to be adherent to the chest wall at the apex, but on minuter examination it was found that there was a large aneurysm springing from the third part of the arch of the aorta on the posterior aspect and concavity, which was inseparable from the lung and could only be detached from the chest wall with great difficulty. It had ruptured into the lung nearly at the extreme apex, which was to some extent consolidated, partly from engorgement and partly from inflammation. The whole aneurysmal pouch was about the size of a cricket-ball, or slightly larger, and had thick walls, especially anteriorly and towards the middle line and below. The interior was very irregular and was covered with deposited clots of varying sizes and shapes. The vessels coming off the arch seemed

¹ Science and Practice of Medicine.

² Sajous' Annual of the Universal Medical Sciences, 1891, vol. i., p. 6.

³ Transactions of the Pathological Society of London, 1892, p. 38.

entirely to have escaped pressure, but the left recurrent laryngeal nerve was found to be tightly stretched and pushed outwards around the aorta. Mr. Armit was much struck with the marked localisation and limitation of the disease to the apex of the left side of the chest. There was no atheroma, calcareous degeneration, or other changes visible in the aorta or other vessels, nor could he find any visceral or other indications of syphilis, gout, or lead poisoning. The spleen, liver, kidneys, adrenals, pancreas, heart, right lung, and bladder appeared to be normal, although very pale. In the pelvis he found a cystic growth, which was adherent to the parietes. This was a medium-sized multilocular cyst of the left ovary, while there was a small cyst in the right ovary. The larynx was not changed. The stomach and intestines contained frothy arterial blood, and were stained, but not ulcerated or otherwise affected.

Remarks by Mr. ARMIT.—It seems to me that an aneurysm of the concavity of the arch of the aorta, situated in the third part, occurring in a young woman who has no other signs of arterial decay, and rupturing high up into the apex of the left lung, is a very rare condition. If she had been examined during life I take it that the altered laryngeal voice (paralysis of the left vocal cord), and perhaps some inequality of the pupils due to the compression of the sympathetic nerve, together with dulness at the left apex, bronchial breathing, a systolic murmur, and perhaps expansile pulsation, would have been the signs that would have led to a correct diagnosis.

HARVEIAN SOCIETY OF LONDON.

Clinical Study of some of the more Important Forms of Abscess.

A MEETING of this society was held on April 4th, Mr. D'ARCY POWER, Vice-President, being in the chair.

Mr. HOWARD MARSH read a paper on the Clinical Study of some of the more Important Forms of Abscess. He began by stating his view that when pus was known to be present in a part it should be evacuated without delay, for not only was it an excretion—something which was outside the pale of the economy, and which could serve no useful purpose—but it did mischief in many ways: by producing tension in acute cases, and in chronic cases by burrowing and by leading to the formation of pockets and tortuous passages lined with granulation tissue, which maintained suppuration and which moreover was often tuberculous. Pus also produced erosion of adjacent structures and might make its way into (a) the large joints, and (b) the large bloodvessels. Mr. Marsh showed nine specimens from the Museum of St. Bartholomew's Hospital illustrating this formidable accident. These included instances in which the three carotids, the thoracic, and the abdominal aorta, the external iliac, and the femoral had been opened by abscesses, and he had known the gluteal and the internal pudic similarly involved. Indeed, there was probably no large artery in the body which had not been opened in this manner. The occurrence was very likely to be fatal. Sometimes the abscess concerned was quite small. As to diagnosis, Mr. Marsh remarked that, though fluctuation was usually depended upon as the evidence that matter had formed, it was a symptom that was available in only a minority of cases—namely, in large chronic abscesses. It postulated several conditions which in acute abscesses were often absent—viz., a sufficient quantity of pus to admit of to and fro displacement, a firm background, pliant superjacent soft parts, superficial position, and absence of great tenderness. In numerous instances of acute abscess several of these conditions were absent. The indications then to be depended on were (a) elasticity, (b) pitting on pressure, (c) the tender spot, and (d) the soft spot. Attention was then directed to particular abscesses. Acute abscesses of bursa should be evacuated before the wall burst and pus was widely extravasated; and in glands before the capsule burst and the surrounding connective tissue and skin were involved. A very formidable abscess was that beneath the gluteus maximus, which might follow disease of the lumbar spine, the hip-joint, or the sacro-iliac articulation. The great difficulty was that

pus burrowed widely under the muscle and that adequate drainage could not be secured. He had known four such cases to be fatal. Another abscess very likely to produce serious difficulty was the post-mammary. Here wide burrowing occurred and sinuses obstinately refused to heal. He had met with two instances in which the breast had been removed, all other treatment, including free drainage, scraping, and prolonged rest, having failed, after long trial, to secure sound healing. A third variety of abscess referred to was that which follows either tuberculous periostitis of a rib or the periostitis of a rib sometimes met with (as Sir James Paget had described) after typhoid fever. In these cases the abscess is often situated behind the ribs, and can be reached only through an intercostal space. He had lately met with two instances in which a large flattened abscess cavity was found between the costal cartilages and the pleura in the immediate vicinity of the internal mammary artery. In such cases the lining membrane of the abscess must be completely cleared away, drainage provided, and rest and perfect asepsis maintained; otherwise burrowing will continue, and, as he had several times seen, separation of the cartilage from the rib will probably occur. A fourth variety of abscess sometimes lead to a condition the exact explanation of which was apt to escape recognition. When a deposit of tubercle occurred in the deeper strata of the subcutaneous tissue wide undermining of the integument might occur, and one or more sinuses might form which obstinately refused to heal. A boy was lately in hospital who had two sinuses of long duration in the occipital part of his scalp. The scalp was undermined over an area four inches in diameter. The pus contained tubercle bacilli. The undermined scalp was freely divided, so that the whole cavity was exposed. All the granulation tissue was scraped away and the flaps were readjusted. The parts now healed. Similar examples had been met with in the leg (so that the affection closely simulated necrosis of the tibia), in the forearm, and in other parts. The diagnosis is easily made by finding that the sinuses nowhere pass beyond the subcutaneous tissue (none pass through the deep fascia or traverse the periosteum) and by observing also that wide undermining in a horizontal plane has occurred. The treatment consists of complete exposure of the whole cavity, thorough scraping and careful readjustment, and the use of uniform pressure.

Mr. D'ARCY POWER in commenting upon the paper first expressed the thanks of the Harveian Society to Mr. Marsh for the interesting nature of his communication. He then called attention to the great importance which should be attached by every class of practitioner to a thorough knowledge of suppuration, for in no other case did such apparently trivial conditions lead so frequently to great issues. He asked Mr. Marsh whether he would kindly give the society the benefit of his experience upon the question as to whether absolute rest retarded or prevented the formation of abscesses in diseases of the spine and joints. Mr. Power also asked Mr. Marsh whether he would not lay it down as an axiom that it was advisable to endeavour to obtain union by first intention in every case where such a result seemed possible rather than to drain an abscess as a routine proceeding. Mr. Power also asked what Mr. Marsh recommended should be done in cases where large masses of caseating material lay remote from the joint when the patient otherwise appeared to be cured of the disease from which he had suffered. His own method was to evacuate them completely if he thought that he could obtain primary union, but if this was doubtful he left them alone, as he thought that they were much less likely to do harm if left untouched than if they became septic.

Mr. PEYTON BEALE drew attention to the great value and interest of the specimens which Mr. Howard Marsh had so kindly brought illustrative of the bursting of abscesses into large bloodvessels. He related a case which he had had under his care at the Great Northern Central Hospital about two years ago. The patient was a boy aged fourteen who had a sinus of many months' duration leading down to the back of the femur and opening externally on the lower and outer aspect of the thigh. In operating to remove the necrosed bone which existed both the popliteal artery and vein were so rotten from their proximity to the suppurating sinus that they unfortunately burst during the operation, and about three inches of each had to be at once excised. Collateral circulation had of course been established previously, and the boy made a good recovery.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Adjourned Discussion on the Legal Definition of Sewers and Drains.

A MEETING of this society was held on April 8th, Mr. S. R. LOVETT, President, being in the chair.

After Mr. F. Vacher, M.R.C.P., F.R.C.S. Edin., Medical Officer of Health to the Cheshire County Council, had been unanimously elected President for the ensuing year, the adjourned discussion on Mr. H. C. Jones's paper on the Legal Definition of Sewers and Drains was resumed, Drs. T. O. Dudfield, Kempster, R. Dudfield, Willoughby, and others taking part. The question at issue in the numerous cases constantly coming before the Courts of Summary Jurisdiction, many of which are followed by appeals, was really that of the liability of the local authority or of the owners of the property for the abatement of nuisances arising from, and the proper maintenance and repair of, any given structure or channel, the incidence of the liability depending on the decision of the courts as to whether the structure were a sewer or a drain, and the difficulty presenting itself almost exclusively in the cases of the combined drainage of several houses. The statutory definitions of a drain required its connexion—(1) with one house only or buildings within the same curtilage, and communicating with a cesspit or with a "sewer into which the drainage of two or more buildings or premises occupied by different persons was conveyed;" or (2) "the drainage of any group or block of houses by a combined operation under the order of any vestry or district board," &c. This second definition, though contained in the Metropolitan Local Management Act, 1855 Section 250, and in subsequent Acts, was omitted in the Public Health Act, 1875, which was still in force throughout England and Wales beyond the metropolis, although combined drainage was general enough in provincial towns. This omission was to some extent met by Section 19 of the Public Health (Amendment) Act, 1890, which enabled the local authority to take action on complaints made under Section 41 of the principal Act of Nuisances, arising from such drains and to apportion the cost as private improvement expenses, but this Act was an adoptive one, and even where adopted it introduced a new complication by substituting the words "belonging to different owners" for "occupied by different persons." This section not having been incorporated into the Public Health (London) Act, 1891, the question of ownership or occupation did not arise; but besides the ambiguity attaching to the expression "curtilage," on which judges had differed in the case of block dwellings as to whether the spaces between the blocks could be considered as a curtilage or must be deemed a street, there was always the difficulty of proving whether the local authority had expressly approved any particular drain connected with several houses as a combined drain, or not. It appeared that if the approval were given in general terms, or were inferred from the authority having neglected to express any objection of disapproval, such an arrangement was *de facto* a sewer the repair or alteration of which devolved on the authority itself. Doubtless there would in future be greater caution in giving a general or a tacit sanction to such combined drains, but the *onus probandi*, so difficult in the case of buildings constructed ten, twenty, or thirty years ago, should rest on the person seeking to divest himself of responsibility for a faulty arrangement rather than on the ratepayers collectively, as represented by the local authority. The result of the discussion was a unanimous resolution that, in view of the chaotic state of the present laws on the subject, the London County Council should be urged to avail themselves of the powers inherited by them from the Metropolitan Board of Works to make by-laws on the drainage of houses throughout the metropolis. A petition to Parliament for an amendment of the law was also proposed; but, in consideration of the present state of Parliamentary business, was deferred for future consideration.

MANCHESTER MEDICAL SOCIETY.

Case Illustrating the Difficulty of Diagnosing the Exact Position of a Pulmonary Cavity.—Nephrectomy.—Typhoid Fever.—Renal Surgery.

A MEETING of this society was held on April 3rd, the President, Mr. F. A. SOUTHAM, being in the chair.

Dr. THOMAS HARRIS brought forward a patient who in all probability was suffering from a Pulmonary Cavity, but in whom the physical signs were so slight and indefinite as to render it impossible to diagnose the position of the cavity. The patient was a young woman twenty-one years of age, who had enjoyed good health until fourteen months ago, when she was taken severely ill with symptoms of an acute pneumonia. This illness confined her to bed for six months, and she had never been well since. Even during the first three days of her illness she stated that her expectoration was extremely foul and offensive. It was, however, very small in amount to commence with, but when she had been ill three days it gradually increased in amount, and during the next twelve months she stated she had been bringing up about a pint of foul, fetid matter every twenty-four hours. The patient had been under Dr. Harris's observation for about two months, at the commencement of which period she was bringing up twelve ounces of fetid, purulent expectoration in the twenty-four hours, this quantity being more or less evenly distributed during that period, and, except when she first awoke in the morning, there was no part in the twenty-four hours when she brought up a greater quantity than at any other period. The temperature during the first four weeks during which she had been under observation had been irregular, but had never exceeded 102° F. During the last four weeks the temperature had been practically normal, and the expectoration had diminished to five ounces in the twenty-four hours. The only abnormal physical signs which the patient presented were impaired resonance and weak respiration over the apex of the right lung. When she first was admitted to hospital two months ago an occasional sonorous rhonchus and a few bubbles were audible over the same part, but latterly there have been no adventitious sounds anywhere to be detected. The expectoration had been repeatedly examined for tubercle bacilli with negative results. Guinea-pigs had also been inoculated with the expectoration, but no tuberculosis had developed in them. The case was regarded as probably one of a cavity of a non-tuberculous nature in the apex of the right lung, resulting from an attack of acute pneumonia. An exploring needle had been several times introduced with negative results. The case was interesting as illustrating the difficulty which existed in localising a cavity with sufficient precision to warrant the adoption of surgical interference.

Mr. E. STANMORE BISHOP showed a young woman aged twenty-one years from whom he had removed a Hydronephrotic Kidney, and presented the specimen, consisting of a greatly dilated capsule with almost perfect absorption of all secreting tissue. The ureter in this case had an abnormal origin, springing from the lower extremity of the kidney, so that when the latter rotated forwards and downwards, in which position it was found, the ureter became bent over its lower extremity and thus occluded. During the operation the kidney was incised, allowing the escape of forty-eight ounces of fluid, sp. gr. 1002, which contained albumen and chlorides, with small amounts of blood and pus. No calculus existed. The patient made a rapid convalescence, though a measly rash appeared on the third day on the chest, arms, and legs, disappearing on the sixth day. No other symptoms of measles were present. Five weeks afterwards the patient was in perfect health.

Dr. DRESCHFELD communicated some Notes on Typhoid Fever. After having spoken of the difficulty of distinguishing, especially in the fæces, the typhoid bacillus from the bacterium coli commune, he pointed out that occasionally the sputum and (in some cases of pneumo-typhoid) the urine contained the typhoid bacillus, and these secretions, therefore, should be disinfected. In the fæces the bacillus was rarely formed before the eighth or ninth day of fever, and from observations made by Dr. James Richmond in the Pathological Laboratory of Owens College it appeared that a short time (from six to ten days) after the cessation of the fever the typhoid bacilli were no longer present in the fæces. From this it is evident that the alvine discharges from convalescent patients are no longer a source of further infection. Dr. Dreschfeld gave some instances of infection from the ingestion of oysters, and pointed out that typhoid fever might be communicated by other articles of food; that the typhoid bacilli grow very readily and on most vegetables, and these by being washed or watered with contaminated water may contain the germs of fever; insects also by coming in contact with contaminated sewage or with typhoid dejections may carry the typhoid organism and deposit it on fruit. A certain family predisposition to typhoid fever was then recognised.

and an instance was given of such a group where seven members of one family were affected with typhoid fever within a few weeks. As to the treatment of typhoid fever, statistics showed that though the mortality from typhoid fever had very much decreased in England when considered per population (in 1871 the mortality per 1,000,000 was for England 371, for London 267, for Manchester 450; in 1892 it had fallen for England to 137, for London to 102, and for Manchester to 240), the case death-rate, or the relation of the mortality to the morbidity as shown by the reports of some of the largest fever hospitals such as the Metropolitan Asylums Board, the Monsall Fever Hospital, &c., still shows a mortality of over 17 per cent. This compares unfavourably with the mortality observed in some of the large German and American hospitals where the treatment by the cold bath is carried out systematically. As yet the good effect of the antiseptic treatment which is now largely adopted in England, and which has many advocates, is not apparent from the statistics. At the Monsall Hospital, where this treatment had been tried for some time, the mortality somewhat diminished, but was still over 13 per cent.

Mr. G. A. WRIGHT also made some remarks upon recent cases of Renal Surgery.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Ectopia Testis.

A MEETING of this society was held on March 28th, the President, Mr. MAKEIG JONES, being in the chair.

Dr. KEELING showed two Dermoid Ovarian Cysts removed a week before from a married woman aged twenty-seven years who had borne two children. One of the cysts was laid open, showing solid fatty contents interspersed with hair. The patient was making a good recovery.

Mr. SNELL introduced cases of Optic Atrophy following Fracture of the Skull, and other patients.

Dr. PORTER showed a well-marked example of Albuminuric Retinitis.

Mr. MAKEIG JONES showed a woman aged forty-six with Double Optic Neuritis who first came under his notice last year with a tumour of the left upper jaw, which rapidly subsided under treatment with biniodide of mercury. She was next seen about three months ago, when she had severe hemicrania on the left side, which soon got well under the old treatment. She came again last week with the pain on the opposite side of the head, and spasm and pain of the right forearm. There was double optic neuritis, worse on the right side, with old anterior synechia of both lenses. Some months after marriage (twenty-four years ago) she had inflammation of both eyes for months. She had had twelve children and three miscarriages. The first children died directly after birth, and some of the children now alive showed well-marked signs of congenital syphilis.

Mr. PYE-SMITH showed a case of Double Excision of the Hip. The patient was a girl aged ten years. She was admitted into the Sheffield Public Hospital in June, 1893, with symptoms of left hip disease. A long splint was applied, but an abscess formed and was opened in January, 1894. Before this the right hip had begun to show signs of disease; an abscess formed, and the joint was excised on May 16th, 1894. It had quite healed by July 1st. A sinus continuing on the left side this hip was also excised on Sept. 7th, 1894. It was quite healed by Sept. 25th. The anterior incision was made in both cases, the carious head and part of the neck only being removed and temporary gauze drainage being used. The patient was walking about the ward before Christmas, but she caught measles and was removed to the Fever Hospital. When now exhibited she could stand and walk with a somewhat waddling gait and could walk well with the aid of two sticks. There was free movement in the hip in all directions. The wounds were sound, and there was no pain.—Mr. Pye-Smith also showed a man on whom he had operated seven and a half years ago for Spasmodic Torticollis by excising part of the spinal accessory nerve. He had been shown in 1888,¹ and he had resumed work and gradually regained more and more the use of his sterno-mastoid and trapezius muscles.

Dr. CLARKE (Chesterfield) read a paper on a somewhat unusual case of Ectopia Testis.

Dr. ARTHUR HALL and Dr. ADDISON exhibited and demonstrated numerous Physiological and Anatomical Preparations lately added to the museum of the Medical School.

The President, Mr. Arthur Jackson, Dr. Dyson, Mr. Snell, Mr. Richard Favell, Dr. Sinclair White, Mr. Atkin, Dr. Arthur Hall, Dr. Rhodes, and Dr. Addison took part in the discussions.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Treatment of Diphtheria by Antitoxin—Traumatic Stricture of the Urethra—Tumour in the Region of the Sella Turcica.

A MEETING of this society was held on April 2nd, the Vice-President, Dr. ADOLPH BRONNER, being in the chair.

Dr. HONEYBURN read notes on two cases of Diphtheria which he had recently treated with Antitoxin. The first case was a child aged six years, who was seen on Jan. 18th, 1895, suffering from croup. There was no visible membrane; the temperature was 103° F. After the injection of Klein's antitoxin there was a gradual improvement, the membrane being easily coughed up. The second case was a child aged three years with croupy symptoms. The temperature was 101.4°. After the injection of antitoxin marked improvement took place. There was a slight rise in temperature after the injection, followed by a fall to normal. Dr. Honeyburne referred to the importance of making a bacteriological examination in all doubtful cases. After the injection of antitoxin the children were well in two days.—Dr. A. Bronner, Dr. Bell, Dr. Kerr, Dr. Evans, Dr. S. Lodge, Mr. Horrocks, Dr. H. Bronner, and Dr. Goyder spoke on the paper, and Dr. Honeyburne replied.

Mr. HORROCKS described a case of Traumatic Stricture of the Urethra in which he had cut down on and excised the stricture, uniting the divided ends of the urethra with sutures and draining the bladder from the perineum. The wound healed well, and the result was very satisfactory.

Dr. WOOD described a case of Tumour in the Region of the Sella Turcica, which occurred in a man admitted for a fracture of the leg. The symptoms noted were a drooping of the right upper eyelid, dizziness, and mental dulness. The right eye showed corneal opacities and anterior polar cataract, the vision being $\frac{1}{20}$. In addition there were diarrhoea, vomiting, and headache. Later on dysphagia came on, necessitating feeding by means of a tube, followed by left-sided hemiplegia and the formation of a bed-sore on the right buttock. The day before the patient died a discharge of pus came from the nose and mouth. There was no fever. On post-mortem examination there was a tri-lobed enlargement, $1\frac{1}{2}$ in. by $2\frac{1}{4}$ in., of the pituitary body, which did not press on the second nerve, but had eaten its way into the nasal cavity. Microscopically the growth was an adenoma of the anterior lobe of the pituitary body.—Dr. A. Bronner, Dr. Kerr, Dr. Goyder, Mr. Horrocks, and Dr. Major discussed the case, and Dr. Wood replied.

Reviews and Notices of Books.

Clinical Diagrams for Recording Cases of Heart Disease. By GEORGE HERSCHELL, M.D. Lond. London: Baillière, Tindall, and Cox. 1894.

THE graphic method of recording physical signs is of unquestionable value as an adjunct to notetaking. When pursued on a systematic and simple plan it can be made to afford a mass of information which can be appreciated at sight. From time to time various *schemata* have been put forward by clinical observers—as to which we can only say that, as a rule, the simplest are the best. Dr. Herschell in the diagrams he has prepared is evidently of this opinion also. For it will be seen that he gives three chest outlines in order to record respectively in cases of cardiac disease: (a) the areas of pain and tenderness; (b) the areas of murmurs; and (c) the areas of dulness and impulse. By this means he obviates the overcrowding of a single diagram by many signs. The outlines are further marked by vertical lines corresponding to the mid-sternal, parasternal, mammillary, and anterior axillary lines,

¹ Brit. Med. Jour., 1888, vol. i., p. 272.

whilst there are introduced two horizontal lines—viz., one at the line of the fourth rib and the other at the lower boundary of the costal arch. We hardly see the necessity of these latter lines, which do not correspond with the ordinary areas of the chest. Each plate contains, further, a series of outlines to represent the sounds of the heart and their rhythm, which are utilised for the graphic representation of alterations in sounds and murmurs on a plan which, in most respects, is tolerably familiar, and was, if we mistake not, first introduced by Professor Gairdner into clinical medicine. The accompanying figures will explain the use to which they are put. Fig. 1 is the schema

FIG. 1.

of normal heart sounds, of which four reproductions are given to be used for each of the valvular areas. Fig. 2

murmur followed by a diastolic one prolonged into the period of long silence. We have no doubt that these outlines will be found serviceable, and need only add that they are issued in books containing twenty-five diagrams, with or without directions for their use.

Digestive Proteolysis, being the Cartwright Lectures for 1894.
By B. H. CHITTENDEN, Professor of Physiological Chemistry in Yale University, New Haven, Conn., U.S.A. Tuttle, Morehouse, and Taylor. 1895.

THIS book really contains an excellent epitome of the present views held upon the questions concerned in the

digestion and utilisation of the proteid food stuffs. It is a reprint of the author's Cartwright Lectures which were delivered in 1894 before the Alumni Association of the College of Physicians and Surgeons of New York. The processes of absorption and the changes which the products of proteolysis undergo in different parts of the body and their probable fate are subjects which are of inestimable importance, and the publication in the present form of the views of so well-known an authority as Professor Chittenden will be welcomed alike by the pathologist and physiologist. In Lecture I. the author deals with the general nature of proteolytic enzymes and of proteids, in which will be found some very interesting observations on the theories of enzymic action, with special reference to catalysis. Just as water serves as a go-between in effecting certain (or is it all?) chemical changes, so with the proteolytic enzymes, pepsin, and trypsin. "They are the go-betweens, making possible the union of the proteids with water by combining with the proteid molecule, and thus paving the way for both hydration and cleavage." Lecture II. discusses proteolysis by pepsin-hydrochloric acid, with a consideration of the general nature of proteoses and peptones; and Lecture III. is devoted to the proteolysis by trypsin and the absorption of the main products of proteolysis. The concluding remarks of the author on the effects of the proteoses and peptones once they have passed outside the limits of the alimentary tract are of particular importance. "It is very evident," he writes, "that beyond this stage these bodies may be passed about from organ to organ and from secretion to secretion, inducing changes here and there in their course, but suffering very little change themselves. The main efforts of the system are directed to the removal of these unwelcome strangers as speedily as possible, for their marked physiological action renders them somewhat dangerous visitors. As normal products of digestive proteolyses they are never found beyond the limits of the gastro-intestinal canal, but undergo retrogression in their passage through the epithelial cells of the intestinal wall, being presumably converted thereby into serum-albumen, which can be directly utilised for the nutrition of the body, a conversion which is plainly dependent upon certain inherent qualities of the living epithelial cells, and is doubtless of the nature of a dehydration." It is superfluous to commend this book, as we are confident that there is not a student of this subject who has no need to be conversant with the views of an authority of the standing of Professor Chittenden.

Archives de Physiologie Normale et Pathologique. Directeurs: MM. CH. BOUCHARD, A. CHAUVÉAU, and J. MAREY. Cinquième Série. Tome VI. No. 4. October, 1894. Paris: G. Masson.

THIS, the last, part of the sixth volume of the *Archives de Physiologie* contains, besides some extracts, the following original articles:—1. Researches on Heterogeneous Osseous Graft, by M. A. Mossé. 2. On the Alterations in the Number and Size that occur in Erythrocytes with Varying Altitude, by Dr. A. Mercier, in which it is shown that in accordance with the observations of Viailly residence at great altitudes greatly augments the number of the red corpuscles in the blood. 3. Further Researches on Shock, by M. H. Roger. 4. New Measures of the Electrical Conductibility and Physiological Work of the Nerves, by Professor Aug. Charpentier. 5. On the Prolonged Resistance of Highly Vascularised Tissues to Gastric Digestion, by M. Ch. Contrejean. 6. On the Cause of Death after Extirpation of the Supra-renal Capsules, by Nicolas di Dominici of Naples. 7. On the part played by the Adiabatic Transformation of Gas in the Performances of Registering Apparatus for Compressed Air, and on the Pulsation of the Ventricles, by M. Ch. Contrejean. 8. Physiological Observations on a

Velocipedic Record, by Dr. Philippe Tissé of Bordeaux. The course was a long one, upwards of 350 miles, and was accomplished in twenty-four hours with an injudicious dietary, but without injurious fatigue. 9. Researches on Muscular Respiration, by M. J. Tissot. 10. On the Progressive Changes in the Air occurring during Asphyxia in a Closed Vessel, by M. Laulanié. 11. On the Excitability of Rigid Muscles, by M. J. Tissot. 12 and 13. Contribution to the Study of the Mechanics of Gastric Digestion in the Bird, and on the Innervation of these Parts, by M. Maurice Doyon. 14. On the Action of the Bile and Urine on Thermogenesis, by M. M. A. Charrin and P. Carnot. 15. On the Vaso-dilator Action of Strychnia, by M. C. Delezenne. 16. On the Optometer of Young, by M. Tscherning. 17. On the Saline Digestion of Fibrin, by M. A. Dastre.

A Pharmacopœia, including the Outlines of Materia Medica and Therapeutics, for the Use of Practitioners and Students of Veterinary Medicine. By the late RICHARD V. TUSON. Fifth Edition. Revised and Edited by JAMES BAYNE, F.C.S. London: J. & A. Churchill. 1895.

TWENTY-SIX years have elapsed since the first issue of the late Professor Tuson's little Veterinary Pharmacopœia, and now it has reached a fifth edition. During this somewhat long period the work has been kept up to the times and has served its purpose, as the present edition testifies. Primarily designed for the use of veterinary practitioners and students, it has not deviated from the original arrangement and is a very handy manual of what it professes to be. The veterinary profession is well supplied with works of this class, but Tuson's book is likely to hold its ground so long as it is edited by such a competent and careful authority as his successor at the Royal Veterinary College, Professor Bayne, who appears to have accomplished the task entrusted to him with judgment and skill.

First Aid to the Injured and Management of the Sick: the Bearer's Companion. By Surg.-Capt. E. J. LAWLESS, M.D. Brux. Edinburgh and London: Young J. Pentland. 1894

SURGEON-CAPTAIN LAWLESS has endeavoured to arrange the subject of first aid instruction to suit the requirements of those attending regimental classes, being of opinion that the "Medical Staff Corps Manual" is scarcely adapted to the more limited needs of a regimental bearer section or of a Volunteer brigade bearer company. The book is divided into two parts, each of which is furnished with an appendix. Part I. deals with First Aid, and is divided into twelve "outline" lessons, which the author hopes will be of use not only to members of volunteer and of civil ambulance classes, but also as a syllabus from which surgeon-instructors and lecturers may elaborate their courses of lectures. Part II. treats of Sick Nursing, Field Hospital Organisation, the Elementary Principles of Health and of Sick Diet, &c. The stretcher exercises, wagon, and handcart drill are taken from the Medical Staff Corps Manual of 1893. In the preface Surgeon-Captain Lawless suggests to the committee of the St. John Ambulance Association that it should introduce a scheme to encourage its certificated pupils to volunteer for Brigade Bearer Company Service. He thinks that there are many men who will not enroll as ordinary volunteers but who would serve as "ambulance soldiers," and that in our county towns the sixty men, with a knowledge of "first aid," could be enrolled to form the brigade bearer companies our Volunteer brigades are so much in need of. We think this an excellent suggestion. The book has been carefully thought out, but it appears to us to contain more information and more technical knowledge than are necessary for the public or for an "ambulance soldier." Like other books of the kind lately published, it errs in that it goes too deeply into many questions which should, in our opinion, be left to the qualified practitioner of medicine. It sets forth in some portions a knowledge which we believe to be dangerous in half-educated hands. The

Appendix to Part I. consists of questions and answers. They may serve a useful end, and they certainly suppose a knowledge more suitable to the public than the text of the book would lead us to expect. The chapter on Equipment exhibits some truths which the Volunteer authorities will do well to take to heart. The Appendix to Part II. contains a Bearer's Form of Sick Report for Medical Office and a Table of Poisons. The latter cannot, we take it, be intended for a medical officer, but it certainly is far too deep for a non-professional person. The book will prove a help to the instructors of military ambulance classes; it is illustrated with forty-nine engravings and is sufficiently indexed. The "get-up" of the book is a credit to the firm which issues it.

New Inventions.

AN IMPROVED CLINICAL THERMOMETER.

MR. JAMES J. HICKS of Hatton-garden has forwarded us a specimen of his "Climax" Clinical Thermometer. The principal obstacles to perfection in previous clinical thermometers were the divisions and figures: firstly, because being cut on the surface of the glass they might hold dirt, and possibly convey infection; secondly, because constant wiping was apt to remove the black and make it impossible to read the figures and divisions until they had been recoloured. These two obstacles have been overcome by the "Climax" thermometer. The divisions and figures, instead of being cut on the glass, are placed on a separate transparent scale which is inserted in the body of the thermometer. The readings are therefore clear, distinct, and will never fade, while the risk of conveying infection is minimised, because the surface of the thermometer, being perfectly smooth, can be easily rendered aseptic. At night-time, by holding the thermometer with its back to a candle or other light, the divisions and figures are easily read. The price varies from 60s. per dozen to 108s. per dozen, according to whether the instrument has a magnifying tube or not, and also whether the bulb is made specially sensitive or otherwise.

AN IMPROVED MULTIPLE LINEAR SCARIFIER.

EVERYONE who has used Squire's scarifier must have experienced the difficulties of cleaning the instrument and rendering it aseptic. Messrs. Mayer and Meltzer have overcome these drawbacks, and have made for me an instrument with such improvements as have added greatly to its value. The blades, ten in number, are double-edged and are fastened to the arms of the handle with two bolts, which are held in position and secured by milled heads. The arms are prolonged to a quarter of an inch from the points of the blades and act also as a guard. This instrument can be taken to pieces, cleaned, and put together in a few minutes, and I have used it with most satisfactory results in lupus and rosacea.

A, The blades.

G. STOPFORD TAYLOR,

Hon. Physician to the Liverpool Hospital for Cancer and Skin Diseases.

THE LANCET.

LONDON: SATURDAY, APRIL 20, 1895.

IN countries which serve as the breeding ground of cholera—that is to say, in those climates where the disease may be said to be indigenous and where all the natural agencies, conditions, and influences are favourable to its development—it is only to be expected that the agencies outside man should come to be regarded as its sole manufacturers and disseminators. But in order to trace satisfactorily the progress of this and other epidemics disease has to be studied on a small scale where the number of its factors is reduced to a minimum. The history of cholera as a large epidemic has to be deduced from the aggregate of a number of authenticated data about its movement in relation to time and space. The steps of its progress can be more accurately followed in countries where the disease may be regarded as an imported exotic, and by the observers of a local outbreak which possibly forms a very small part of a general epidemic. The number and seeming complexity of the phenomena present during an epidemic are in themselves confusing; it is impossible to ascertain all the conditions and to separate the relevant from the mass of irrelevant facts. That there are some agencies present of which we are still ignorant, in what is called “a cholera year,” which are absent in other years, must, we think, be admitted by all who will compare the remarkable statistical differences between them. In India, for example, the figures for 1892 and 1893 serve to mark the marvellous difference between an epidemic and non-epidemic year. But it is at this point that the volume just issued by the Local Government Board, embracing a series of reports and papers on cholera in England in 1893, with an introduction by Dr. THORNE THORNE, the medical officer of the Local Government Board, is so valuable. The reports and papers deal with small and not overwhelming numbers. They take up the history of the disease in this country, trace out its introduction and connexion with importation, its relation to the results of bacteriological researches and local conditions, public water services, and states of public health. They furnish, in short, information which could only be obtained by the combined labours of skilled inquirers.

Dr. BARRY gives a summary account of the disease in England in 1893. There were in all sixty-four localities involved, of which fifteen were metropolitan sanitary districts. The total number of attacks was 237, and of these 135 terminated fatally. In most of the affected localities—that is to say, in forty-two out of the sixty-four—only single cases occurred. The mortality rate of those attacked reached 47 per cent. The first definite case of importation of cholera into England in 1893 was in June, and others followed; but it is worthy of remark that there was no extension of the disease from these cases. It was in August at Great Grimsby that the earliest indications of cholera in England occurred, and at the adjoining district of Cleethorpes, and almost at the same time the disease appeared

at Hull. There is no doubt that there was ample opportunity for the introduction of cholera into these Humber port towns in 1892 and subsequently, but the precise time and method of its introduction and the exact date of its earliest manifestations cannot be definitely fixed. Dr. THORNE THORNE is probably quite right in thinking that cholera had made its way into Grimsby and Cleethorpes and acquired a foothold there some time before the fact was recognised. Dr. REECE, in his report on this outbreak, acquits the water service, but attaches importance to the influence of faulty conditions of sewerage and drainage. The probable diffusion of the infection by “trippers”—there were 235,000 excursionists in the six months from May to October booked to Grimsby and Cleethorpes by a line of railway—is described and illustrated in maps showing the topographical distribution of cholera in England during 1893. But one of the most interesting and important points raised in the report is in connexion with the alleged exposure of the oyster beds at Cleethorpes to the effluent from the town sewers, and the suspicion that oysters and other shellfish may have contributed to the diffusion of the disease. About this Dr. THORNE THORNE expresses himself very cautiously and contents himself with remarking that, so long as there is any risk of shellfish being exposed to any such pollution, it is impossible to assert that their use as an article of diet may not be concerned in the production of this class of disease. It is right to add that a correspondent writing to the *Standard* of the 15th inst. states very emphatically that the “set” of the tides at Grimsby and Cleethorpes is such that no taint can possibly be conveyed to the oyster beds from the sewage. Still, the subject is well worth further investigation.

There is one lesson which the medical history of 1893 teaches—viz., that it is impossible to devise any method which shall prove a perfect safeguard against the introduction of cholera into different places, and that it is not so much the introduction of such cases as the local insanitary conditions and surrounding circumstances affording a means for the diffusion and development of the infection that have to be feared. We cannot devise a net for catching disease germs, but we can clear away all muck-heaps in which they can germinate and grow. The fact that there were so many solitary attacks, or attacks limited to two or three cases, is very creditable to our English system of public health administration and to the methods designed and adopted by the Health Department of the Local Government Board.

We must not omit to add that the volume submitted by the medical officer of the Local Government Board is illustrated by a number of maps and plates of a very thorough and exhaustive kind, and affords abundant evidence of the care and ability which have been brought to bear upon the various subjects of which it treats. It must be consulted by all who are interested in the history of cholera in this country in 1893. It contains also a history of the diarrhoeal outbreak at Greenwich Hospital and the observations of Dr. KLEIN on the reputed cholera material submitted to him for examination and report.

IN a remarkable passage of his interesting and now famous book, “The Foundations of Belief,” Mr. BALFOUR discusses the relative part played by reason and authority in

regulating the opinions and practices of mankind. As many of our readers are no doubt aware, the distinguished writer holds the view that authority is the dominant factor, and that the influence of reason *quâ* reason is comparatively insignificant. "At every moment of our lives," he says, "as individuals, as members of a family, of a party, of a nation, of a Church, of a universal brotherhood, the silent, continuous, unnoticed influence of authority moulds our feelings, our aspirations, and our beliefs. It is from authority that reason itself draws its most important premises. It is in unloosing or directing the forces of authority that its most important conclusions find their proper function. And even in those cases where we may most truly say that our beliefs are the rational product of strictly intellectual processes, we have in all probability only got to trace back the thread of our inferences to its beginnings in order to perceive that it finally loses itself in some general principle which, describe it as we may, is in fact due to no more defensible origin than the influence of authority." In a later passage Mr. BALFOUR affirms that "it is Authority rather than Reason to which, in the main, we owe not religion only, but ethics and politics; that it is Authority which supplies us with essential elements in the premises of science; that it is Authority rather than Reason which lays deep the foundations of social life; that it is Authority rather than Reason which cements its superstructure." With Mr. BALFOUR'S views on ethics, politics, and religion we are not concerned, but we may without presumption inquire how far these somewhat sweeping statements are true of science, and more particularly of our special field—*viz.*, medicine.

That the great majority of mankind take their views on science second-hand—*i.e.*, on authority—is no doubt quite true—is, in fact, almost a truism. We all believe that the earth goes round the sun, but it is only the minority who understand or consciously realise the reasonings by which COPERNICUS upset the Ptolemaic astronomy. Every educated person knows that bodies are attracted towards each other directly in proportion to their mass and inversely as the square of the distance, but comparatively few have followed and deliberately accepted the Newtonian argument. We all know that the blood contains innumerable myriads of tiny corpuscles, but comparatively few have verified the fact by microscopic examination. This is almost self-evident even without the help of Mr. BALFOUR'S stately and sonorous periods. But is it a true inference from these facts that our views on the solar system, or on gravitation, or on the composition of the blood are non-rational or extra-rational? Surely not. We accept a certain view, not in deference to the authority of COPERNICUS or NEWTON, but because we know that the proofs in support of those views are accessible to us if we choose to look into them, and that they are competent to support the conclusions drawn from them. Science knows nothing of authority *quâ* authority. Her most precious maxims are search, inquire, observe, see for yourself, accept nothing without evidence; but science is long and life short, and the bulk of mankind have neither the time nor the capacity to undertake the observations and experiments necessary for the verification of the scientific doctrines which claim attention.

The place of authority in medical science is without doubt a large one. The influence of HIPPOCRATES was immense, widespread, and is by no means even yet exhausted. GALEN ruled the Middle Ages in medicine as truly as AUGUSTINE ruled them in theology. In modern times the Brunonian Theory had an immense vogue quite incommensurate with its merits, and at the present day the Germ Theory insensibly permeates all our views on pathology. There are reasons why the influence of authority is necessarily greater in medicine than in the exact sciences. We cannot bring medical theories to the touchstone of experience and proof as we can bring a fact of astronomy or chemistry. Life is a mystery; disease is an even greater mystery; and it is idle to expect that theories in pathology or therapeutics can be subjected to any offhand or decisive experimental test. The facts are too numerous, too subtle, too closely interlocked to permit of rapid and secure conclusions. Hence the life-long observation and the slowly accumulated experience of a great physician or surgeon possess an intrinsic value, and medical science would be much the poorer if this were not so. But the appeal is always to the fact and not to the dogma, to nature and not to the teacher. In medicine we are ever engaged in a double process—*viz.*, accepting a theory or working hypothesis and subjecting it to constant test and revision. We accept the germ theory on authority, but the practical fruits of asepsis and antiseptics admit of daily experiment and observation. We believe that salicin or nitrite of amyl or strophanthus is a valuable remedy in the first instance on the authority of a distinguished teacher or experimentalist, but ultimately on the results of our own individual experience. Medicine, like other departments of science, does not encourage a blind submission to authority, but rather impels her votaries to the daily accumulation of fresh facts and the daily trial "whether these things be so." A reverent scepticism is the only possible frame of mind for the sincere scientific inquirer. He looks on nature solely with the view of penetrating her secrets, and he accepts every demonstrable fact, no matter how unwelcome or how inconvenient.

It is in the field of therapeutics that the influence of authority is the most potent and perhaps most pernicious. The abuse of blood-letting and mercury are melancholy examples of the evil effects of authority in medicine. We should ever be on our guard against accepting any sweeping dictum unless we can support it by solid evidence. There is no doubt at the present day much routine therapeutics that is simply traditional, and many drugs in the Pharmacopœia are there by "divine right" of custom and authority rather than by personal merit. But at the present day authority is everywhere on the wane, and the tendency is in all cases to refer theories to the test of experience. We should be sorry if the influence of so distinguished a writer as Mr. BALFOUR were thrown entirely into the scale of authority—at least, in the field of science. Science has her adherents, her devotees, her martyrs, but she has no priests. She opens her arcana to all who will patiently look upon them. Patience, humility, and labour are the keys which unlock all her treasures. The true practitioner of medicine must chiefly "practise"—suffering humanity permits him no choice in the matter—but he will also observe, test, accept,

reject, and press towards the goal of surer knowledge and higher art. He will as little as may be lean on authority, and trust as much as possible to the daily patient investigation of the laws and processes of nature.

WE print to-day the third of Dr. BLANDFORD's Lumleian Lectures on the Diagnosis, Prognosis, and Prophylaxis of Insanity, and we are certain that this, the concluding one, will be found by our readers as lucid, learned, and informative as its predecessors. The subject-matter of these addresses lends itself agreeably to comment, for it invites debate from all directions. Questions of fact and questions of fancy, the laws of our country and those of WEBER-FECHNER, education with its dilemmas, heredity with its fallacies and its truths, religion, and therapeutics are all involved; and if the politician and humanitarian find serious food for reflection in these problems, no less does the humourist, whether bitter satirist or broad jester, see in them material for the exercise of his wit. Every discussion on insanity must invade the province of the highest physiology, where the outcome of exact knowledge is supplemented or obscured by transcendental speculation, while it must be prepared to deal with points of material detail whose redemption from triviality and even comicality will only be apparent to those who know. It is not our intention to follow Dr. BLANDFORD from point to point in these interesting topics, for the admirable clearness of his lectures makes all exposition unnecessary; but we desire to commend his remarks upon the tyranny of the modern examination system, which were received by the Royal College of Physicians of London with uncompromising approbation, to the close attention of our readers, so suggestive and important do they seem to us.

"I have seen," says Dr. BLANDFORD, "disastrous effects from pressure of examinations upon boys and girls. They fail to pass or they fail to gain the prize for which they are competing. The end of all the long and wearisome toll of cramming and grinding is failure. Many breakdown in the mere preparation and never get to the examination point. Every school and college and other educational institution must hold out a number of money prizes as baits to catch pupils but the ordinary pass examinations are divided and subdivided till their number is multiplied indefinitely, and the student has constantly in front of him an examination in some subject or other on which for the time he must concentrate his whole mind, but which is to be completely thrown aside as soon as it is passed, when another has to be taken up in its place." These words must not be construed as a sweeping indictment of modern educational methods in general, for it must be remembered that the speaker is only alluding to cases where there exists some predisposition to nervous breakdown. He is not denying that there are very many—an immense majority—of our young people perfectly able to stand the tests which the examination system of to-day lays upon their intelligence, their temper, and their self-restraint. He recognises that for the many who are normal the trials are not necessarily too severe. These need come to no harm, and often thrive mentally and bodily under a discipline to which

they are able to properly respond. And it is equally obvious that those who are abnormal—those who are mentally deficient or unstable—will not acquit themselves with satisfaction in higher examinations, and that the attempt to compel them to do so may be fraught with mournful consequences. So far the question is simple enough, as questions always are simple where the extremes are concerned. But when the medical man is called upon to advise in a case where the mental qualities of the student are not displayed to casual view, where the want of ballast or balance is by no means evident, his proper course may be difficult to see. And such cases are not infrequent, and possibly are growing in frequency. For to us Dr. BLANDFORD's view, that *a priori* reasoning would lead to the supposition that nervous disease is increasing among us as the environment in which we are now living becomes more complex, and thus induces a corresponding complexity of brain centres and functions with more and more instability and liability to disorder and deterioration, seems sadly reasonable. And upon this it follows that there must be with us now a larger class whose possible nervous breakdown is all in the natural order of things, even though there are not enough symptoms present to the eye of the parent to arouse suspicion and perhaps almost nothing subjective or objective from which the medical adviser can predict the impending trouble. How far should his desire to employ proper methods of prophylaxis against a tendency to nervous breakdown lead a medical man to preclude a boy or girl from entering upon a competition, or a series of competitions, while he knows that every lucrative avenue of modern life is barred by examinations?

We do not ask with any idea of attempting to answer—a general answer can be given—but only with the intent to bring before our readers the seriousness of the position in which the medical adviser may find himself, and to urge upon them, in the spirit of Dr. BLANDFORD's words, not to give way to any parental optimism that the child will grow out of "it," where "it" is a sign of mental insufficiency, but to lean ever to the side of caution, and to recommend in such cases the abatement of examination tests. When such an audience as that before which Dr. BLANDFORD was speaking receives with applause words of warning against the possible evils of educational pressure, the existence of such evils must be held proven. It becomes, therefore, the duty of every practitioner to whom the welfare of a child is confided to deal boldly with the point. The question of money, of a career, possibly of a brilliant future for the child, will be very clear to every parent, so that the advice to withdraw a boy or girl from competitions, success in which should enable him or her at an early age to achieve independence, will not be received gratefully by any parent unless it can be enforced by accurate demonstration of the good sense of the recommendations. And in many cases it is impossible to demonstrate to the layman the slender signs and unsubstantial symptoms upon which the advice has been based. Nevertheless, it is the practitioner's duty where he has a child to deal with who exhibits in character or mannerism any evidence of nervous instability to insist that to force such a child upon a course of examinations is to court for him or her a terrible fate.

Annotations.

"No quid nimis."

THE RESEARCH SCHOLARSHIPS OF THE GROCERS' COMPANY.

It will be probably well known to such of our readers as it most urgently concerns that applications for appointment to these scholarships must be made during the month of April in each year, so that this seems to us a fitting time to briefly announce the conditions under which they are granted. The scholarships have been designed as stipends for those engaged in research into the etiology and possible preventive treatment of important diseases. Candidates, who must be British subjects and at their first candidature under the age of thirty-five, must apply for appointment to the Clerk of the Company, Grocers' Hall, E.C., during the month of April, and such application must be accompanied by an exact statement of the nature of the proposed research and unexceptionable testimonials as to the candidate's ability to conduct the same. The Court of the Company reserve to themselves all discretion as to the appointments, taking every pains to estimate the relative importance of the subjects of research brought under their notice, and in particular the relative probability that the research would result in the desired increase of knowledge. In appointments to scholarships preference within certain limits will be given to gentlemen already holding scholarships who desire to continue their work, this preference being dependent, of course, upon the advances made in the research. All researches are to be conducted under conditions of time and place satisfactory to the Court, so that reasonable facilities may be given to the Court for observing their progress. In bringing these facts before our readers we are only echoing, we are certain, their thoughts when we compliment the great City Company on its enlightened benevolence.

QUASI-MEDICAL IMPOSTORS AND THE PRESS.

EVERY charlatan must congratulate himself that his commerce in the fears and the credulity of mankind is so lightly regarded by public opinion. It matters not that his medicalisms may be as old or older than his generation, and may have done service in medical practice to the limited extent of their powers before his very being was thought of. It is of no moment that his diagnoses, like his knowledge and like the testimonies of his grateful "patients," are of the most imaginative character. If he will profess enough and loudly enough, truth apart, he may long remain the adored of numerous dupes. If he should err—and in this respect he is most human—he has ample dexterity in handling excuses. The Press overflows with his self-laudation and with the gibes which, emboldened by his own great ignorance and that of a simple multitude who worship him, he casts at the honest labour of scientific medicine. It must ever appear to instructed persons a marvellous thing that men of this type should thrive as long as they do by the practice of such open and unabashed imposture. Yet, after all, the success of their speculations is not unaccountable. In order to explain it we have to make due allowance for the action of shrewd and unscrupulous business capacity upon the minds of simple and unsuspecting people, many of whom are still to be found everywhere. We must remember, too, that the principle of *caveat emptor* continues to rule the affairs of daily life. This explains the complaisance with which many tales of diseases treated by the magic of some quack mixture, showing in every line the evidences of fabrication, are published at length in the daily press. How far this principle may be allowed to carry us is a question as yet unfortunately not settled by any legislative order. When, however, we find

that journals of repute and authority are capable of lending their space without comment to the base purposes of a nostrum-seller, we cannot but feel that an offence has been committed against many readers who are accustomed to trust them as competent sources of information. It is clearly undesirable that medical practitioners, even if blessed with that leisure which they lack, should engage in barren argument with irresponsible persons who admit not even the premisses of scientific teaching. It is their still higher privilege to show, by the skill and care of their methods, as well as by the firm and judicious exercise of that authority which must go with their knowledge, what can and also what cannot be accomplished by the art which they practise. In so doing we consider that they are justified in expecting to receive the frank support of all sections of the Press without the addition of insinuations published by mercenary wonder-workers.

THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

WE announced last week the appointment of Dr. G. Seaton Buchanan as a medical inspector of the Local Government Board. Quite apart from his relationship to Sir George Buchanan, late medical officer to the Board, his claims to consideration were very high. His medical career has throughout been a very distinguished one; he is a Doctor of State Medicine in the University of London, and he has for several years devoted himself to the practical study of the infectious fevers and of the work of a medical officer of health. He is certain to maintain the traditions which marked his father's successful official career. But we regret to say that the vacancy, which was created somewhat suddenly and unexpectedly by the resignation of Dr. Hubert Airy, was due to increasing ill-health on Dr. Airy's part. Dr. Airy has done work in relation to epidemiology and to the etiology of disease of which any worker may feel satisfied; and if he has of late years undertaken duties which, though not of less importance, have brought him less than formerly under public notice, it has been due to slow but increasing failure of health. In his retirement he will carry with him the kindest recollections and sympathy of all his colleagues; and many others who will recall him will have in recollection a cultured and refined personality which always secured for him the friendship and esteem of all who were capable of appreciating his high qualities. We can only wish for him all the enjoyment which may be possible, in view of the circumstances with which his retirement from public office is associated.

THE IDENTIFICATION OF BLOODSTAINS.

THE third volume of *Medico-Legal Studies*,¹ compiled and recently published by the Editor of the *Medico-Legal Journal*, New York, contains an interesting epitome of the present position of our knowledge bearing upon the identification of bloodstains. In regard to chemical tests—the guaiacum test and the production of crystals by the addition of common salt and glacial acetic acid (Teichmann's crystals)—it is stated that these several tests, while reliable in determining whether the matter examined contains blood or not, are of no value and throw no light whatever upon the question as to whether it was the blood of man or of animals that was examined. The application of the exceedingly delicate instrument, Sorby's spectroscopic eye-piece, is next described, and it is said that by its means the late Dr. Richardson of Philadelphia was able to detect the 3000th part of a grain of blood on an axe-handle supposed to have been used in a case of murder. The succeeding section, on the value of the microscope in the differentiation of the blood of man and of domestic animals, contains a really valuable collection of material which

¹ *Medico-Legal Studies*, vol. iii., by Clark Bell, of the New York Bar and Editor of the *Medico-Legal Journal*, 67, Broadway, New York. 1885.

every medico-legal practitioner would do well to have by him. The illustrations are not a matter for congratulation, but the tables of the micrometric dimensions of the blood corpuscles of mammals are useful. On the whole, the conclusion—which is founded upon the evidence of well-known toxicologists like Professor Theodore Wormley, Professor Reese, who edited the American edition of Taylor's "Medical Jurisprudence," Dr. Richardson of Atlantic City, Dr. Stevenson of Guy's Hospital, and others—appears to be that with a skilled and careful microscopist and a good instrument of high powers it will generally be possible to distinguish a human bloodstain from that of any of the lower animals with the possible exception of the guinea-pig and opossum. This subject is, however, one upon which it is well known that there exists a diversity of opinion amongst the leading authorities.

SWALLOWED HALFPENNIES.

A DEATH is reported from Chorley of a young woman who eight years ago swallowed a halfpenny, but had suffered no inconvenience from it. Death was caused, according to the paper, by sudden sickness and the consequent rupture of a bloodvessel. She vomited a green corroded halfpenny. *A propos* of this case a corroded and attenuated halfpenny has been shown us with the following authentic history. A boy three years old on Nov. 12th, 1874, swallowed a bronze halfpenny. Consultations were held, but the coin neither passed nor could be reached. Occasionally he had difficulties of swallowing, which he had to overcome by stretching his neck to one side and changing his position, but otherwise he had no pain or inconvenience. At an early stage of the case he used to bring up a little stained mucus. On Sept. 21st, 1888, the halfpenny was brought up unexpectedly and without effort or vomiting, the boy having swallowed it just thirteen years and ten months previously. He has since been entirely free from symptoms. The halfpenny was very thin and light and gave the impression that it might have been gradually dissolved had it not been so happily got rid of. Its weight was 57 grains, that of a new bronze halfpenny being 86 grains.

THE DEATH AT ROCHFORD WORKHOUSE.

AN inquest was held at Rochford Workhouse on Wednesday, April 3rd, when certain facts were elicited that seem to us to call for more publicity among medical men than they have yet received. Charles Phillips, a pauper inmate, died on the previous Saturday after removal from the padded cell attached to the institution. Dr. L. L. James, the medical officer of the workhouse, stated that the death occurred from erysipelas, the result of injury and shock. Evidence went to show that Phillips was not of sound mind. He was not in the slightest degree violent, but simply old, feeble, and childish, and as he was seen to fall down twice against his bed, once striking his head against the locker, it is not suggested that the injuries were other than self-inflicted accidents. But the immediate cause of the shock which contributed to the sad end was made the subject of dispute at the inquest, under circumstances which did not display the guardians of the parish in an attitude of particular wisdom. The patient had been removed to the padded cell upon instructions received by the master of the workhouse and unknown to the medical officer. The cell was a cold, indiarubber-lined chamber, badly ventilated, and therefore most unfit for the reception of an aged, enfeebled, bruised man, and the evidence of the medical officer went to show that the removal of Phillips to it on two extremely cold nights contributed to his death. The jury concurred in the medical officer's view, returning the following verdict: "The deceased died from erysipelas

resulting from injury to the eyes, which was purely accidental, and also caused by being removed from the warm infirmary to the cold padded room," and adding to it a rider to the effect that in their opinion the guardians should have consulted the medical officer before putting deceased into the padded room. The rider is one that we entirely approve of. Padded rooms are useful in a course of treatment in certain cases, and their employment, like all other details of medical treatment, should be strictly under the physician's jurisdiction. They are designed to assist the patient by preventing him from injuring himself, and it is an absolute abuse of their purpose to transform them into convenient places for the irresponsible stowing away of the sick. The insufficiency of the nursing staff of the institution was also revealed at the inquest, as the evidence went to show that three old feeble paupers, "one of whom had to be accommodated with a chair," had been told off to take care of others so sick and helpless as to require constant attention.

"MIND THE WHIP."

THE resident medical officer of the County Hospital at Durham sends us a note, which we publish in another column, on a sad accident which has happened before and will happen again—whose infrequency, indeed, strikes us as almost remarkable. The patient while walking beside a cart with a friend suddenly felt that he had been struck in the eye, intense pain and total blindness being the result. A foreign body in the interior of the globe having been diagnosed the eyeball was removed, and a knot of whip-cord discovered embedded in it. This is an accident against which it would seem impossible to guard, and many of us must shudder to think that it has been no fault of our own or of our cabman that it has not happened to ourselves. In particular is it an accident likely to happen to the rider in hansoms, for he cannot see the movements of the driver, which certainly conduce not infrequently to the smart flicking of the fare over the face through the open window. From the expected blow, even though the period of possible expectation be of the briefest, the interior of the orbit is generally safe, for the first wincing movement is to close the lids. But the rider in hansoms gets no warning at all. When we attempt in our mind to estimate the number of people carried in hansoms during, say, a year, and, drawing upon personal experience, credit a large proportion of them with an unexpected stripe from the whip across the face, we wonder that more eyes are not sacrificed to the unskilful or careless brandishing of the hansom cabman's whiplash.

THE EXAMINATION OF SCHOOL CHILDREN'S THROATS.

THE prevention of the spread of infectious disease through the agency of schools is certainly one of the most difficult duties which devolve upon the medical officer of health. On the one hand, he is prompted to school closure or the exclusion from school of children from infected localities or houses; and on the other he is anxious as far as possible not to interfere unduly with the educational work of the institution and the prospect of the Government grant. In many instances it is obviously no easy matter to determine which course to pursue. In this connexion we note that Mr. Wellington Lake, the medical officer of health of the Guildford and Woking rural districts, has recently made a practice of examining the throats of children on the reassembling of the schools in his district, and it must certainly be said—as, indeed, we have frequently pointed out—that there is much in favour of this course. Mr. Lake uses for his purpose nickel-plated tongue depressors, several clean

towels, and a laryngeal mirror; and after the inspection of each child's throat the tongue depressor is carefully cleansed in a basin of hot water, the contents of which are frequently changed. This cleansing of the spatula is a very important point, and too much care cannot be exercised. Boiling water would theoretically be the safest course, but there are certainly practical difficulties in the way of using it—such, for instance, of maintaining the water at boiling point and cooling the spatula after immersion. Probably Mr. Lake's method carefully carried out is all that is necessary, though perhaps the immersion of the spatula in a disinfectant solution and then in the hot water would be a course better calculated to disarm theoretical criticisms which have to our knowledge been made. Mr. Lake's plan is to exclude from school every child presenting the least signs of a sore-throat, and he has succeeded in keeping most of such cases from school until the throat has become normal. In cases of enlarged tonsils or elongated uvula he advises removal. Mr. Lake reports that since he has adopted the measures above referred to he has noticed a remarkable diminution of diphtheria in those districts where the disease formerly persisted, and that the occasion for school closure does not seem to arise either from diphtheria or scarlet fever, as in addition to the above measures he exercises a rigid control over infected houses and their inmates. Mr. Lake points out that to some extent his practice plays havoc with the school attendance as it necessitates excluding all cases of sore-throat, however trivial. He thinks, however, that the Education Acts should be adapted to the times, and that children excluded by the medical officers of health should, for statistical purposes, be regarded as having continued their attendance.

THE ORAL INSTRUCTION OF THE DEAF.

A MEETING composed of medical men and others interested in the education of the deaf and dumb was held on the 5th inst. at 26, Golden-square, for the purpose of hearing a lecture from Mr. S. Schöntheil, for many years head master of the Jews' Deaf and Dumb Home, on the most modern and scientific method of training the deaf and dumb, so as to enable them to use articulate speech and to give them a full command of language. The lecturer opened the proceedings by introducing several of his pupils and testing the results of their training by exercises in pronunciation, lip-reading, dictation, recitation, reading, and answering miscellaneous questions. Through this searching ordeal the pupils passed very successfully. Most people are aware of the enormous difficulty entailed in teaching the deaf to speak; where a child is stone-deaf the obstacles are greatly enhanced and the intonation is apt to be specially faulty. In this respect Mr. Schöntheil's pupils acquitted themselves with marked success. The lecturer explained that in the case of several the instruction imparted to them had first of all proceeded on a faulty basis, and that in consequence they had been compelled to unlearn much that they had first learnt. Nevertheless, steady progress had been since achieved, and the results were considered very promising by the experts present. Mr. Schöntheil then expounded in his paper the aim of the oral method to restore the deaf to the society from which his defect tends to cut him off and laid special stress on the endeavour which he considered ought to be made to avoid distortions of the face and raucous sounds. After giving examples of the lines of thought by which the instruction of the deaf was to be conveyed, he concluded with pointing out the strong necessity for having properly trained teachers of the deaf and for devoting special and individual attention and kindness to each pupil. Mr. Charles E. D. Black, formerly secretary to the Royal Commission on the Deaf,

testified to the high opinion formed by the Commissioners of the results of Mr. Schöntheil's teaching, and added that he had no doubt that with the more favourable conditions under which, as he understood, Mr. Schöntheil was now working, the results which would be attained would be even more successful than heretofore.

THE ROYAL COMMISSION ON TUBERCULOSIS.

It will be remembered that this Commission was appointed in July, 1890, with the following reference: "To inquire and report what is the effect, if any, of food derived from tuberculous animals on human health, and, if prejudicial, what are the circumstances and conditions with regard to the tuberculosis in the animal which produce that effect upon man." This reference resulted from the desire of the Government to obtain an authoritative scientific opinion on the public health aspect of the question before it could deal with the numerous complaints made by meat and milk traders of the great diversity of practice in dealing with this class of food that exists in different places. The Commission of 1890 met under the chairmanship of Lord Basing, the other members being Professor Brown, Sir George Buchanan, Dr. Payne, and Professor Burdon Sanderson. On Lord Basing's death in October of last year the experimental inquiries of the Commission were not completed, and the Commission was reorganised with Sir George Buchanan as chairman. We understand that this Commission has now agreed upon its report, which will be presented to Parliament in the course of next week.

THE CLINICAL RESEARCH ASSOCIATION.

WE have received the small handbook of the Clinical Research Association, Limited, in which are carefully and clearly set forth the aims of the association and its methods of work. As there seems to be some little misunderstanding as to the objects and position of this association the appearance of this little work is well-timed, and we cannot but think that many of those who take the trouble to study its pages will come to the conclusion that it will be advisable for them to join the association. The Clinical Research Association has for its object the provision of a clinical laboratory equal to, or better than, many of those connected with the various schools of medicine and hospitals; which laboratory shall be open for the carrying on of the work required by those engaged in general practice who, with the best will in the world, have neither time nor opportunity to make those irregular or tedious observations which are often required to complete a diagnosis. Such a laboratory has often been suggested, but the difficulty of carrying on, side by side, original investigation for the sake, merely, of what is to be found out and the same investigation in return for a definite fee has always cropped up. We are glad to see, however, that the association has taken the bull by the horns, and has laid down the proposition that in pathology and clinical research the labourer is worthy of his hire just as much as when the same labourer is feeling a pulse and writing a prescription. The work of the association is not done for old pupils, for old teachers, or for personal friends, and, therefore, a fee is expected for each investigation as surely as one is expected for a consultation. The association undertakes to examine sputum for tubercle bacilli and for other micro-organisms, for lung tissue, &c. The examination of urine, blood, pus, vomit, and faeces is undertaken; tumours and diseased tissues are investigated, and specimens taken from the throats of diphtheria patients are examined and analyses of drinking water and poisons are made. Although the fees for these examinations appear to be somewhat low we suppose that the association can afford to send good reports in consequence of the number of specimens that they have to examine. In

fact, it is acknowledged that a large proportion of the examinations which are undertaken could not possibly be reliable at the price charged unless the association received a large measure of support from the profession, so that a number of examinations of the same character may proceed side by side. The association already numbers over 850 members, and over 2300 specimens have been examined and reported upon during the past six months. This is an exceedingly good record, and the association, if it continues to be as well managed as it apparently is at present, should ultimately be very successful indeed. Through its agency the best opinions are placed at the disposal of every member of the association, and the gain to diagnostic accuracy arising from such work must be enormous. We wish the association the success it deserves.

THE REAPPOINTMENT OF MEDICAL OFFICERS OF HEALTH.

WE have called attention in our columns from time to time to the insecurity of these appointments, and for the benefit of the community it would be well if the Local Government Board would formulate some regulations which would prevent the annual reappointment of such officers. To subject the medical officer of a district council to annual re-election is an anomaly which ought not to exist and practically is an incentive to avoid doing anything which might offend some of its members. Last week Mr. Hannah, the medical officer of health for Abram, a colliery district in Lancashire, retained his appointment by the casting vote of the chairman only. He has held the appointment for nineteen years and discharged the duties conscientiously and with great ability; no fault could be found with him in this respect. He has, moreover, been subject to annual re-election. This time the new district council advertised the appointment, and an opponent was brought in the field—with the result that the casting vote of the chairman was required for Mr. Hannah to retain the appointment held so long by him. Why should the health officers (medical officer and sanitary inspector) be the only officers subject to such a rule? Why not the clerk and surveyor also? Even the board itself is not subject to an annual re-election. Medical officers of health should now bestir themselves in regard to the tenure of their appointments.

ON CATCHING COLD.

MARK TWAIN once wrote a paper pointing out the appalling danger of going to bed as exemplified in bills of mortality. For one person who died out of his bed several hundreds succumbed in bed, and now we have Mr. Ashby-Sterry drawing attention to the same thing. Hitherto he has hymned in graceful verse pantaloons, frills, and the tempestuous petticoat, and now, *quantum mutatus ab illo Hectore*, he lauds the pyjama. In a recent number of the *Graphic* he says:—

"I have a theory that most people catch cold at night after they are in bed, and it is to this fact I attribute a great deal of the violent colds, the bronchial catarrhs, and influenza which have recently been so prevalent. The temperature goes down suddenly in the night, and people catch cold when they are asleep without knowing it. This evil is to be counteracted, not by piling on a lot of heavy blankets, but by wearing thick, close-fitting garments of a pyjama-like nature and warm socks on the feet. If this system were adopted I am quite certain that it would be found beneficial."

There is common sense in this. People unquestionably may catch cold in bed, especially if they are at all restless and so kick the bedclothes off. In that event, if only clad in a thin cotton nightshirt, they are sure to catch cold, whereas if clad in pyjamas, not necessarily thick but made of some woollen material, the chance of a chill is much lessened. Our ancestors, even as late as the eighteenth century, went to bed, as Malory centuries earlier phrased it, "as naked as

a needil"; but only the hardiest of them survived. We, however, are cast in more tender moulds, and require protection by night as well as day. The feminine portion of the community will, we fear, not adopt Mr. Ashby-Sterry's suggestion, for though, as an eminent authoress once remarked, "a woman looks so down-trodden in her nightdress," still that vesture offers opportunities for ornament which pyjamas, at best unlovely garments, never do. Perhaps the Rational Dress Society may take the matter up, and Mr. Henry Holiday might turn his attention to devising a really artistic as well as hygienic night-gear.

THE AGE-CONSTITUTION AND THE DEATH-RATE.

THE closer dependence of the death-rate on the age-constitution than on the sanitary condition of a community, rendering it absolutely necessary to reduce the former to a common standard before any conclusions can be drawn as regards the public health, is well known to statista, but little understood by the general public or their local representation. A striking illustration is given by Mr. May, medical officer of health for Aston Manor, in his report for last year. The age-constitution of the population as given at the last two censuses was:

	Under 5 years.	5—10	10—15	15—25	25—35	35—45	45—55	Over 55
1881	157	131	110	191	156	113	74	68
1891	127	123	119	204	162	113	68	74

This enormous reduction in the child population and relative increase of ages between fifteen and thirty-five, those of lower mortality, is wholly due to a continuous decline in the birth-rate during the last fifteen years, which has shown itself in a reduced death-rate, and more palpably in the fact that, though the population had increased between 1881 and 1891 from 53,842 to 68,633, the demand for school accommodation was almost stationary. Thus far the change in constitution has had an apparently favourable influence on the death-rate, but if it continue to operate it will lead to an accumulation of persons over forty-five years of age and be followed by a steady rise in the death-rate, however excellent the sanitary condition of the district may be, when the authorities will be as eager as they are now unwilling to have the recorded death-rates "corrected."

MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS.

AT a recent meeting of the London School Board a report of the school management committee was adopted to the effect that three medical men should be appointed to examine cases in which medical certificates were produced to account for non-attendance at school. Whether it is supposed by the members of the Board that medical certificates are forged by parents who desire to keep their children from school we are not informed; but that seems hardly likely to be the explanation, for the detection of a forgery would not require the services of a medical practitioner. It is, indeed, hardly possible to avoid the inference that the Board has thus put a slight upon the medical profession by affirming the necessity for the supervision of the certifying medical practitioners in respect of this trivial matter of school attendance. We are sorry to be driven to this conclusion, and we feel that in view of it we may fairly invite the majority of the School Board to reconsider their decision. The men whom they refuse to trust in this small matter are the same men to whose absolute discretion and approved skill the weightiest matters are unreservedly entrusted both by law and the custom of society. It is something new and by no means agreeable to the profession at large to have a

municipal body arrogating to itself the right to appoint overseers and to criticise in this way the discharge of our professional duties, and we may add that such interference actually attempted would not only provoke strong and just resentment on the part of the medical men, but would certainly result in the adoption of measures to make that sentiment effective. Upon this point the Board would seem to be very vulnerable, seeing that Mr. Diggle has pointed out that the Board has no power to enforce the presentation of a medical certificate at all. To give it, therefore, is purely a courtesy on the part of the medical attendant, and if this courtesy is to be made the occasion of vexatious interference on the part of the Board all that he will have to do in self-defence will be to refuse the certificate and inform his patient that the Board has no power to exact it.

THE DIFFUSION OF SMALL-POX.

THE three weeks which have elapsed since we noticed this subject have been weeks of quiescence of small-pox in England, whilst Wales has been, practically, entirely free from the disease. In London, in the three weeks ended with Saturday last, April 13th, there were but 25 fresh cases of small-pox and not one registered death therefrom. The patients remaining under treatment at the close of any one of those weeks have never exceeded 60 in number, and were last Saturday below 50. These data are eminently satisfactory, especially in so far as the type of the disease is concerned. Both Peterborough and Bedford, which have contributed cases in the period under discussion, have apparently got rid of threatened trouble, and nearer home the suburbs have escaped also and almost without exception. In the Midlands the Manor of Aston, the city of Birmingham, and Smethwick have had experience of small-pox, but to a very limited extent, though Wolverhampton had multiple attacks last week. Derby, while registering one death, has had no fresh cases so far as we can learn. Liverpool has had but some half dozen cases, and not one death. Northward, we learn of the invasion of South Shields and Jarrow, about a dozen cases within the past month being recorded in the two towns. In Dublin, whilst matters are mending as compared with former periods, there has not been much decrease in the last fortnight and the first week of the present month, though taken collectively the total of admissions was only 58, as against 95 in the three weeks next preceding. The end of the third week of March found 58 acute cases and 100 convalescents under isolation, whilst the close of a fortnight later found only 120 under isolation, though the acute cases had risen to 63. During the three weeks there were 9 deaths, of which 2 were in vaccinated adults aged over twenty years, and 7 in unvaccinated persons, 1 aged under five and 1 under twenty, the remaining 5 being in adults aged twenty years and over.

A MATTER OF ETIQUETTE.

In our issue of April 6th we commented upon the remarkable views held by the majority of the vestrymen of St. George's, Southwark, as to the ethics of one medical man visiting the patients of another. Dr. Waldo declined to do this without the consent of the medical man in charge of the case. The matter was referred to the Works Committee, and at the vestry meeting held on the 9th inst. the following resolution of this committee was read: "That in any case where the surveyor is of opinion any suspicion is attached to an employé he shall notify the medical officer of health, who shall accordingly visit the man, the vestry undertaking to be responsible for any irregularity in respect thereto." Dr. Waldo refused to allow himself to be compelled to commit such a breach of medical etiquette and the matter was referred back to the

committee. The object of the vestry is to prevent malingering, and in this resolution the committee practically say they can trust neither their employ nor his usual medical man. We can imagine the howls of virtuous indignation which would arise if the ratepayers held a meeting and passed the following resolution: "That in any case when the ratepayers are of opinion any suspicion is to be attached to one of their employés"—we take it that a vestryman is an employé of the ratepayers—"the medical officer of health shall be notified, and shall accordingly visit the man, the ratepayers undertaking to be responsible for any irregularity in respect thereto." Vestrymen are but human; they are sometimes ill, and have been known to attend vestry meetings and committee meetings irregularly; although, being unpaid employés, the ratepayers could not adopt the suggestion of the vestryman who said: "Nothing acts so nicely on a sick man as for him to be on half-pay. It does more good to him than medicine." Dr. Waldo will have the sympathy not only of his professional brethren but of every other right-thinking man in the stand he is making for the unwritten canon which governs the relations between medical men.

THE LEICESTER BACTERIOLOGICAL INSTITUTE.

IT has on several occasions been laid down that there should be in every populous centre in the kingdom a bacteriological laboratory in which might be conducted investigations of various kinds, for the same reason that every municipality now finds it essential for its complete official equipment to have a public analyst and laboratory. Of the large Midland towns, Leicester has been the first to provide such a laboratory for the training of resident medical men and others in bacteriological methods and to make provision for the examination of pathological and bacteriological specimens. This laboratory, which has been fitted up by Messrs. J. Richardson and Co., Limited, has been placed under the direction of Dr. J. A. Turner, the medical officer of health. In the prospectus before us nothing is said as to work already done, but the objects for which the institute is established are (1) to investigate the means for preventing and treating the various infectious and other diseases, and to provide a place where original work may be carried on for this purpose; (2) to provide instruction in bacteriology to medical men and advanced students, especially for those residing in the Midlands; (3) for the diagnosis of disease by means of bacteriological and other processes; and (4) to prepare, supply, and test any protective or curative material. The scheme is sufficiently ambitious, but there can be no doubt that under energetic and judicious guidance it may be brought to a successful issue, though we think that there will have to be a little more definiteness and crystallisation of idea as regards the aims of the institute than can be gathered from the prospectus sent out.

THE HOLLOWAY SANATORIUM INQUIRY.

WE have received from Dr. Charles Mercier a letter on this subject. The letter itself is too long for insertion, and part of it refers in detail to evidence adduced at the recent inquiry held by Mr. Gally, Q.C., and Dr. Savage, on which we have purposely avoided commenting until the report of the commissioner and his assessor is published. The inquiry, it will be remembered, was held apparently as a direct consequence of an extremely violent attack made by several newspapers on the character and management of the institution generally, on the ground that in one case a coroner's jury had reported that in their opinion "the medical supervision had been insufficient, and that the mechanical restraint was excessive and too long continued." The most important part of Dr. Mercier's letter is an emphatic and dignified protest, with which we most cordially agree, against the licence of language which the writers of these journalistic articles

have employed without adducing any evidence to justify them. He quotes such phrases as: "If ever in this world a poor helpless wretch was done to death by inhuman barbarity and criminal negligence that man was T. W.—. In all the blood-stained annals of modern lunatic asylums there is not to be found a more sickening and horrifying story." "It is a story of the slow torturing to death of a helpless maniac by methods the barbarity of which must be apparent to the most callous observer. The perpetration of such a crime," &c. Dr. Mercier points out that neither at the coroner's inquest nor at the recent inquiry was there any attempt to prove such abominable charges, "nor even to repeat them before the very tribunal which is constituted for their investigation." Exaggeration and profusion of abusive epithets do harm and tend to cause a reaction even when there is a good case; and where they are used from imperfect acquaintance with the subject and from hasty interpretation of facts they are sure to recoil sooner or later on those who unjustifiably employ them. The care of the insane is one of the most anxious and wearing occupations which a medical man can follow. The medical officers of our asylums are a body of men second to none for humanity and the constant display of practical sympathy. They deserve and should be able to rely on public coöperation and support in their difficult and delicate work, and we regret and deprecate extremely the gruesome language which many modern journalists allow themselves to employ when speaking of useful institutions and of the physicians in charge of them.

THE annual dinner of the Volunteer medical officers will take place at Limmer's Hotel, George-street, Hanover-square, on Wednesday, April 24th, at seven o'clock, when Sir Wm. Guyer Hunter, K.C.M.G., will preside. Those intending to be present should communicate as early as possible with Surgeon-Lieutenant Eddowes, M.D., mess secretary, 25, Old Burlington-street, W.

WE continue our report of the thirteenth meeting of the German Congress of Internal Medicine. We have before now had to criticise the proceedings at scientific gatherings on account of the obtrusiveness of the picnic element, but this Congress is, and has always been, a quiet and thoughtful meeting of medical men, and from its joint deliberations practical good has before now resulted.

WE have received the report of the inquiry held by Major Cardew into the circumstances connected with the recent explosions on Southwark Bridge. The responsibility seems, on the surface, to be about equally distributed between the Electric Lighting Company and the Gas Company: but we shall return to the matter later.

THE right carotid artery and the third part of the right subclavian artery were simultaneously ligatured on Tuesday last by Mr. Page in the Royal Infirmary, Newcastle-on-Tyne, for innominate aneurysm. This is the first time that this operation has been performed in that hospital.

Pharmacology and Therapeutics.

FLUORIDE OF SODIUM AS AN ANTISEPTIC.

La Semaine Médicale of March 20th says that fluoride of sodium has been used with success by Dr. Tuffier of Paris in cystitis, and more recently by Dr. Blaizot of Doulon-lès-Nantes, in the form of an aqueous solution of the strength of 1 in 100 or 1 in 200, as an antiseptic wash for the bodies of patients suffering from infectious disease, as a mouth wash, as a vaginal injection in chronic or subacute vaginitis, and in the treatment of erythema in newly born infants, in which it

was very efficacious. It possesses the property of dissolving albuminous substances, which may possibly account for its good effects. It cleans the skin exceedingly well and gives rise to a delightful feeling of softness and coolness, both when employed externally and when applied to mucous surfaces—as, for example, when it is used as a mouth wash, for which it is eminently suitable.

PHYSIOLOGICAL AND THERAPEUTICAL EFFECTS OF CONDURANGO.

The physiological and therapeutic effects of condurango and conduragine, which is not an alkaloid but a resinogluco-side of a complex nature, have been studied by a large number of European and American observers during more than twenty years, but there is still great want of agreement amongst them.¹ The most remarkable observation on the physiological action of condurango which has been made is perhaps that of Dr. Guyenot, whose experiments in Dr. Dujardin-Beaumetz's laboratory in the Hôpital Cochin in Paris led him to believe that this drug exerts a toxic effect on the nervous system, but not until twenty-four hours after its injection into the body. This may possibly afford an explanation of the somewhat contradictory results reported by previous observers. It may be remarked that Gianuzzi and Buffalini ascribed to condurango tetanising powers. Lauder Brunton² found that when the preparation employed is deprived by filtration of the coarse particles of the bark no tetanic symptoms are produced, though when these are not removed the injection of the watery extract into the jugular vein causes an animal to die with opisthotonos. As to the therapeutic effects of condurango, the observations in the Hôpital Cochin fully confirm what has been stated by many observers as to its usefulness in ulcer and cancer of the stomach in relieving the gastralgia, catarrh, hæmatemesis, and vomiting, and in improving the appetite; but lend no support to the statements made by Drzewski, Barkman, Barth, and others that it actually cures cancer of the pylorus. According to K. Wagner³ the effect of condurango on the digestive functions of dyspeptics and cancer patients is slight and inferior to that of nux vomica, while it is quite incapable of producing much effect on the gastric juice. According to Chelissoff it is the pancreatic juice and the bile that are chiefly increased. Condurango may be administered in powder, decoction, tincture, or wine.

EFFECTS OF CURDS ON INTESTINAL PUTREFACTION.

According to K. Schmitz⁴ cheese and curds as well as milk and kephir exert a marked anti-putrefactive action on the proteid matter in the intestines. This subject has been recently investigated by Dr. Gaseroff⁵ in Professor Chudnovski's clinical laboratory, St. Petersburg, the subjects of the nine series of observations made being all healthy and well-developed hospital employes. He found that under the influence of curds the absolute quantity of ethereal sulphates was diminished—in some instances by as much as one-half—and that the ratio of the ethereal to the preformed sulphates was increased; also that the weight of the body increased. His results point to the retardation of putrefactive processes in the intestine by curds, though whether it is really the casein or, as Schmitz is disposed to believe, the lactose which is the active agent must still be looked upon as an open question.

TANNIN IN ENTERITIS.

Tannin, though a very valuable and powerful drug, has, when given in large doses, so serious an effect on the stomach, producing nausea and vomiting, and, indeed, almost cauterising the mucous membrane, that its use is necessarily much restricted. Professor Meyer of Marburg, however, recently discovered a combination of tannin with acetic acid which passes through the stomach unchanged, and, therefore, without doing any injury, but on entering the alkaline intestinal tract it breaks up, tannin and acetate of potash being formed. That this has a very powerful effect on the intestine was shown by experiments on animals, and subsequently by clinical observations in Professor Müller's polyclinic in Marburg, of which a short account is given

⁵ Vrach, March 2nd, 1895.

In an article by Dr. C. Künkler.⁶ There were forty-one patients, mostly children, who nearly all suffered from chronic enteritis. Many of them had been already treated with but little success by means of naphthalin and bismuth, but they were all, as far as could be ascertained under the conditions of out-patient practice, very greatly benefited, most of them, indeed, really cured, by tannigen. Dr. Künkler recommends that at the commencement of an attack of enteritis a powerful disinfectant, as naphthalin or calomel, should be given in combination with the tannigen, and that the latter can subsequently be continued for some little time after the catarrhal symptoms have passed off in order to allay the irritability of the intestinal canal and to guard against a possible return of the attack. Tannigen, which is a yellow, tasteless, insoluble powder, must not be given in milk but in boiled water or oatmeal grouts (Hafergrütze). It has been shown to be quite harmless in doses of forty-five to fifty grains, but generally three to seven and a half grains per diem are sufficient. The children in the polyclinic were ordered a grain and a half to three grains three times a day, infants a few weeks old taking the smaller dose; older children and adults were sometimes given the larger dose, and occasionally as much as seven and a half grains.⁷

SALIPYRIN IN MENORRHAGIA AND METRORRHAGIA.

The value of salipyrin in various forms of uterine hæmorrhage, which has been noticed by Zurbelle, Kayser, and Bigelow, has been very carefully tested by Dr. E. G. Orthmann by observations on thirty-two patients in Dr. Martin's polyclinic in Berlin.⁸ Fourteen were cases of purely functional menorrhagia. In three the menorrhagia was associated with salpingitis and oöphoritis. In the remaining fifteen the hæmorrhages were irregular, and were classed under the head of endometritis hæmorrhagica; four of these were associated with metritis, perimetritis, or oöphoritis, four more were consequent on parturition or abortion, and the rest were due to previous operations on the tubes or ovaries. The salipyrin was always given in the form of lozenges containing fifteen grains each. The patient took three daily, commencing a day or two before the hæmorrhage was expected and continuing them throughout the whole time it lasted, the total number of lozenges taken being from twenty to seventy. With respect to the results observed, in the severe menstrual hæmorrhages a marked improvement occurred in seven cases, and a complete cure was effected in two. The pain associated with the hæmorrhages was also greatly relieved. Of the four cases of metrorrhagia complicated by metritis, perimetritis, or oöphoritis two were improved, as also were all those following parturition or abortion, but there was much less success with the operation cases. Of the whole thirty-two cases twenty were more or less beneficially influenced by the treatment, the most marked success being obtained in the simple menorrhagia subsequent to parturition or abortion. In no instance were any of the unpleasant by-effects ascribed to salipyrin observed, not even when seventy lozenges were given. Dr. Orthmann thinks the results observed are quite sufficient to warrant his recommending other practitioners to give salipyrin a trial in suitable cases of uterine hæmorrhage.

LORD CROMER'S REPORT ON EGYPT, 1894.

THE British Consul-General's annual report on the finances, administration and condition of Egypt during 1894, is much shorter this year than usual, occupying only fifteen foolscap pages against twenty-one in 1893 and thirty-nine in 1890, when for the first time Lord Cromer (then Sir Evelyn Baring) drew up a comprehensive statement explaining the general progress of administrative reform. There are, however, several appendices by the head of the Public Works Department and other officials, which collectively take up about as much space as the main portion of the document.

According to his invariable custom Lord Cromer commences with revenue and expenditure, and in a few short paragraphs recapitulates the entire history of Egyptian

finance since 1882.¹ Now, although as a rule questions of finance do not enter within our province, still as it is unquestionably true that money and sanitation are inextricably associated we may be excused for devoting a short space to this section. In the first place, we cannot refrain from expressing our admiration at the extremely lucid treatment by Lord Cromer of what he very rightly calls a complicated subject. It would be impossible to be more explicit, and at the same time explanatory, within reasonable limits. At the end of 1894 the excess of revenue over expenditure for the twelve months amounted to no less a sum than £E.785,000, or considerably more than three-quarters of a million sterling, the Egyptian pound being equal in value to twenty shillings and sixpence. When the estimates were framed the anticipated surplus was set down as £E.530,000, but owing to enhanced receipts and lessened disbursements "the net result was £E.255,000 better than the estimate." These figures, as Lord Cromer further observes, may be considered as very satisfactory, but unfortunately there is a reverse side to the medal. As the outcome of influences, chiefly international, which are all explained in the clearest possible manner, "the real available surplus for 1894" amounts to £E.155,000 only; the balance—"namely, £E.630,000—cannot, for one reason or another, be touched by the Egyptian Government" without the unanimous consent of the Powers, a consummation devoutly to be wished, but which, unfortunately, "there seems to be little prospect of securing."

As regards the future, with especial reference to the possible provision of any considerable sum for sanitary work, the outlook cannot be said to be encouraging. The Estimates for 1895 provide for a nominal surplus of £E.660,000, but the real surplus is not expected to surpass a paltry £E.11,000. With the exception of £E.150,000 "being part of the cost of constructing a dam near Assouan," the *status quo* of 1894 is maintained, but Lord Cromer's explanation of the reasons that compel this cheese-paring cannot be gainsaid. "The agricultural depression, coupled with the artificial embarrassments due to the international engagements into which the Egyptian Government has entered have produced a situation which renders the exercise of strict economy more necessary than ever. The execution of some public works, which would have been of great benefit to the Egyptian population, may have to be postponed. The same may be said of other administrative reforms which would involve an increase of expenditure. If prices fall still further the difficulties of the situation will naturally be aggravated, but at present I see no reason for alarm in connexion with the financial situation. Nothing has as yet happened to inspire doubts as to the continued solvency of the Egyptian Treasury. The Egyptian Government, in spite of the international engagements by which its freedom of action is curtailed, should be well able to deal with the present difficulties of the situation."

In common with all who wish well to Egypt and desire to see our intervention in her affairs crowned with success, we can only bow to the inevitable and hope for better times. In this connexion the pertinency of some further remarks by Lord Cromer must be generally admitted. "It is essential that all who are in any degree responsible for the administration of Egyptian finance should bear in mind that the first and greatest interest of the people of Egypt is to maintain the Egyptian treasury in that position of assured solvency which, after great efforts, was secured only a few years ago. Any measures which would endanger that position, or which would in any way shake the credit of Egypt, are strongly to be deprecated. The revenue must be made to balance the expenditure. The commencement of a new floating debt is above all things to be avoided."

There is no denying the cogency of Lord Cromer's contention, and yet, on the other hand, it is equally impossible to avoid thinking that the immense reserve funds which at the present moment belong to Egypt and are allowed to remain comparatively unproductive might be utilised to the utmost advantage for the execution of urgent sanitary and other works. That Lord Cromer shares this opinion is evident, but he does not care to discuss the question at length, because any remarks he might make upon it "might only serve to increase the irritation which unquestionably exists in connexion with the manner in which the subject has been treated." Amongst other important—well nigh essential—measures, the drainage of Cairo has to

⁶ Allgemeine Medicinische Central-Zeitung, Feb. 13th and 16th, 1895.

⁷ For Prof. Meyer's original paper see Deutsche Medicinische Wochenschrift, Aug. 2nd, 1894.

⁸ Berliner Klinische Wochenschrift, 1895, No. 7, quoted in Allgemeine Medicinische Central-Zeitung, 1895, No. 25.

¹ By an obvious error this date is printed 1892 in the report, and yet in more than one English newspaper the mistake is rather unpardonably perpetuated.

be relegated to an undated future, and yet "the redundant balances held, in one form or another, by the Egyptian Government" amounted on Dec. 31st, 1894, to no less a sum than £ E.4,127,000.

Prisons.—Turning to matters more legitimately within our province, it is highly satisfactory to find the following encomium of a department that may be said to have been created by the present administrator: "In few branches of the Egyptian administration has greater progress been made during the last few years than in the prison department, of which Dr. Crookshank is the director-general. Those prisons which have been built under Dr. Crookshank's superintendence by prison labour can bear comparison with any similar institutions in Europe." This is very high praise indeed, but it is thoroughly well deserved. Crookshank Pasha has been in Egyptian employment ever since the beginning of our occupation, and at one time, because he had not performed impossibilities, he had to withstand a vast amount of adverse criticism which unhappily was not altogether confined to quarters whence it might reasonably have been expected. Tenacity and determination in a good cause are, however, not unusual characteristics among our countrymen, and in the present case these qualities were developed in a marked degree. The result is most encouraging, and we trust that at no distant date the Director-General of Egyptian Prisons may have the satisfaction of administering a department as near perfection as possible in every respect. At present, however, for causes entirely beyond the control of Crookshank Pasha, there is still much to be desired. "Overcrowding, with all its attendant evils, still exists in the provincial prisons; neither can it cease until considerable sums of money, which it is impossible for the Government to provide at present, are spent. A portion of the General Reserve Fund might very usefully be devoted to the construction of new prisons." Lord Cromer's concluding remarks on this subject will be read with interest. "The prison receipts amount to about £E 2000 a year, which are employed in improving and extending existing prison accommodation, but this is not nearly sufficient to meet the requirements of the department. I am glad to be able to add that a sum of £1500 has been granted for the adaptation of an existing building at Alexandria to the purposes of a small juvenile reformatory capable of holding from 100 to 150 boys. An institution of this sort is much required. It is impossible to go over any of the prisons in Egypt without being struck by the youth of many of the prisoners, who should certainly on every ground be separated from adult offenders." It is very much to be desired that the reform here indicated should be extended so as to embrace the entire country. The herding of juvenile offenders with hardened criminals cannot but be productive of the most serious consequences. Egyptian children as a rule are bright, intelligent, and well disposed; if preserved from evil associations the majority of the youthful delinquents would doubtless grow up into reputable members of the community. Quite recently we heard of a society that was got up under British auspices for the protection of Egyptian donkeys and horses, a most desirable object no doubt; but would it not be better if the benevolent people who want to benefit Egypt were to direct their energies and their subscriptions towards some scheme for the amelioration of their own species? A Juvenile Rescue Association for Egypt would have ample scope, and if well directed could not but be productive of a vast amount of good.

Sanitary Department.—Here, too, Lord Cromer apportions praise in no stinted fashion. "The remarks which I have made in respect to the Prisons Administration apply equally to the Sanitary Department. Under the intelligent direction of Rogers Pasha much progress has been made. New dispensaries have been opened. The number of patients treated in Government hospitals has increased. An infectious diseases hospital at Cairo has been completed. An English specialist is about to be placed in charge of the lunatic asylum. Three new hospitals at Damanhour, Fayoum, and Beni-Souef are in course of construction. Slaughter-houses are being built in several provincial towns. A Vaccine Institute has been completed. Sixty-six mosques have been placed in a sanitary condition; 121 cemeteries have been dealt with under the Cemetery Decree passed in January, 1894." All this indicates considerable progress and is very satisfactory as far as it goes, though, of course, as Rogers Pasha would be the first to admit, the general insanitary condition of the country

remains practically unchanged. All comes to those who know how to wait, however, and perhaps in time the Director-General of the Sanitary Department may be given the means to accomplish the thorough cleansing of Egypt. It is certainly true that the thin end of the wedge has been inserted. The sanitation of mosques and cemeteries is an undoubted indication of better things to come, and Lord Cromer's last observation in this section, though vague, is encouraging—"It is to be hoped that some portion of the General Reserve Fund will be eventually devoted to sanitary improvements." Elsewhere the Consul-General writes: "But the department is much crippled for want of funds. Thus Rogers Pasha writes to me: 'It is an undoubted fact that the population is beginning gradually to appreciate the advantages of medical institutions, whether hospitals or dispensaries. Demands are now constantly made for the creation of new dispensaries and hospitals throughout the country, and it is a matter of the deepest regret that the resources of the department should be so limited as to prevent these demands being complied with.'"

When the Egyptian Government dispensaries were first started in 1887 a mistaken idea seems to have prevailed that it was hoped to make money by them. Even Rogers Pasha seems to have entertained this opinion, for in his first annual report (1892) he writes: "The dispensaries of the country are worked at a loss. . . . The general failure of the dispensaries." The idea really was to vulgarise—as the French say—the knowledge of European modes of treatment amongst the *fellahin*, and in this way help in the general work of reformation. The budget allotted to the Sanitary Department did not admit of the multiplication of hospitals, so the dispensaries were adopted as a sort of compromise. It is very satisfactory indeed to find now that the population is beginning to value these much criticised institutions and that their number is being added to.

VENEREAL DISEASE AND SANITATION AT DOVER.

IN respect to the prevalence of venereal disease among the troops and the attending social circumstances, it would be difficult to find a greater contrast than that afforded by the town of Dover as compared with Aldershot. At the latter town, as already explained in these columns,¹ much of the trouble is due to the fact that the soldiers start from there for foreign service, and that Aldershot is the place where soldiers who have married without leave are too often compelled to abandon their wives. These women, being generally without resources, often drift into prostitution. The soldiers quartered at Dover have, on the contrary, returned from foreign service, or else are young recruits sent there to fill up vacancies in the regiments. Also Dover is a much larger town, and offers much better prospects of employment for any soldier's wife abandoned by her husband. Then Dover possesses charitable institutions which cannot be created in so small a town as Aldershot. Lady William Seymour, for instance, takes very active interest in all that affects, directly or indirectly, the families of the soldiers. No soldier's wife is known to be in distress at Dover, and as the help given is not State help, but organised by private charity, no distinction would be made between women married with or without leave to soldiers. Such a woman, if abandoned, would certainly be helped to return home; and among the women on the town none are known to be soldiers' wives. Nevertheless, there is a great deal of immorality, and one-third of the soldiers in the hospitals are suffering directly or indirectly from venereal disease. Yet even this state of things is considered an improvement on the past. Here, as at Aldershot, everyone agreed that the tone of the rank and file had greatly improved. The men were better educated, cleaner, and more sober. The increase of sobriety is an important factor. When soldiers suffering from venereal disease are questioned they generally connect their illness with some bout of drunkenness; otherwise, they maintain, they would have been able to resist the allurements of the women in the streets.

In spite of this more favourable state of affairs regret is very generally expressed that the Contagious Diseases Acts

¹ THE LANCET, March 30th, 1896.

were abolished. The police especially lament the deplorable effects produced on the conduct and morality of shop girls, servant girls, and other young women which result from the abrogation of these Acts. Formerly, if a young girl was seen constantly in the streets besporting herself with soldiers the police would call on her parents and warn her in their presence. Now the police are absolutely powerless and are obliged to witness scenes which they know full well must generally culminate in immorality without being able even to remonstrate. But the town authorities, especially during the last twelve months, have been displaying more than usual severity in prosecuting the owners of disorderly houses. Much controversy prevails in the town as to the wisdom or otherwise of such action, which may certainly drive the evil more under the surface, but is less likely to diminish its extent. The effect of such prosecutions, it is argued, may act as a restraint on women. If, as some alleged, the Contagious Diseases Act encouraged men to immorality, it certainly had the effect of checking women; and it is now proposed to attain the same end by the alarm which the publicity given to the prosecution of a disorderly house naturally creates. Should, however, this policy prove successful, it will only accentuate that grievance which has so much increased since the abolition of the Acts, and which is now the principal subject of complaint. The fact is that soldiers are less and less inclined to frequent regular prostitutes, but this does not mean that they are any the more virtuous. It means that they court a more respectable class of girls, and thus a countless number of shop girls, work girls, but more particularly of servants, become their mistresses. On this phase of the question a great deal of evidence can be obtained at the homes for fallen women. About a year ago a petition was sent from a home for fallen women at Dover to the military authorities with the initials and particulars of all cases given. These statistics showed that during the previous seven years on an average three out of every four women assisted had been seduced by soldiers. Whether it be a coincidence, or whether some special measures were taken, it so happens that since this statement was made the proportions have completely altered; for out of 37 women received in 1894 only 11 had been seduced by soldiers, and out of the children born 9 were attributed to civilian and only 5 to soldiers. It is generally the youngest and the most inexperienced girls who are the most easily led astray by soldiers, and for them especially the Contagious Diseases Acts were a terror and an effective check. In the discussion that arose on this subject at the International Congress of Hygiene held in London in 1891 it was stated that at the Chatham Lock Hospital 58 per cent. of the women were only sixteen years old; and that the magistrates of that town certified that in spite of the Criminal Law Amendment Act juvenile prostitution was more common since the abolition of the Contagious Diseases Acts. The Poor-law guardians coincided in this opinion. At Dover we were able to obtain details concerning 72 women who had been assisted at a home for fallen women and who had all suffered from syphilis. One of these girls had primary syphilis when she was only thirteen years old. Another had secondary syphilis at the age of fourteen. Another was seduced when thirteen years old, had secondary syphilis when fourteen, and gave birth to a child when fifteen years old. A fourth was violated by her grandfather when eleven years old, was sent to the workhouse, which she left when fourteen, and then contracted primary syphilis; at sixteen she suffered very severely from secondary syphilis, and, though not cured, is now walking the streets of Dover. All these five girls are now well-known Dover prostitutes. Four other girls were fifteen years old; 3 had primary and 1 secondary syphilis; 1 of them gave birth to a child while ill. Eight girls were sixteen years old; 6 had primary and 2 secondary syphilis. At seventeen years 3 had primary and 5 secondary syphilis. At eighteen years 4 had primary and 1 secondary syphilis. At nineteen years 5 had primary and 1 secondary syphilis. At twenty years 8 had primary and 3 secondary syphilis. Thus, out of a total of 72 cases no less than 46 were minors and 8 were under sixteen years of age. Several of these women gave birth to syphilitic children; many of them are now in the streets of Dover. It is well known that they have not been efficiently cured, yet nothing can be done to prevent their spreading the disease among the troops and the civil population. Some persons have expressed the desire to see syphilis placed among the infectious diseases for which compulsory notification is obligatory. It is not necessary to insist on the impracticability

of such a measure. Legislation based merely on sentimental and moral grounds is not likely to meet with much approval. All the State can hope to do is to regulate unwholesome industries, and a woman who earns her living by immorality is pursuing an unwholesome industry that endangers the health of the community, the sufferers being not only the guilty, but also many innocent children, wives, and others. That her victims are in the first instance also guilty of offending against good morals is not the point at issue, since such purely moral offences are not punished by the law. But the law does try to check the spread of disease. The law does regulate and inspect unwholesome industries. There is no law affecting the consumer of bread or of milk, but there are many laws on bakehouses and on dairies. It will be said that the question of morality is not involved in these trades; yet it is wrong, it is opposed to our sense of moral rectitude, to make bread or sell milk under conditions likely to cause ill-health; and it would be equally wrong to encourage such trades by purchasing bread or milk under unwholesome conditions. The law, however, finds it most practical to deal only with the person who trades, who sells, and not with the purchaser. Now there are women in the streets of Dover who are known to be diseased who obtain their living by means that spread this most serious disease; and though a milkman who kept his milk near an open drain would at once be prosecuted nothing can be done against these women. In the meanwhile, the British taxpayer has to supply an enormous sum for the maintenance of an army, though the effective strength of this force is very considerably reduced by the prevalence of venereal disease among the soldiers.

In respect to general sanitary matters Dover again affords a complete contrast to Aldershot. The ground, far from being new, has been inhabited for centuries. But if for ages the soil had been contaminated it was one of the first towns in England to avail itself of the Sanitary Act of 1848. When this law was enacted the corporation at once set to work to replace the tub system then in vogue by a general system of drainage. Though there was not in those days half the present population Dover spent £80,000. To overcome the insufficiency of level a pumping station was established in the lower part of the town, which raised the sewage so that it can flow into the sea by gravitation. It is, however, only necessary to pump two hours before and two hours after high tide. The outfall is between the Admiralty Pier and the Shakespeare Cliff, and its length has been extended several times. The original loan raised for drainage purposes was paid off thirty years ago, and Dover boasts of being not only one of the first towns to adopt the system of drainage, but also of having been the first to pay off its debt. The waterworks are likewise a municipal enterprise. Wells were sunk in the chalk near the Castle. The water is pumped up into a reservoir. It is very pure water, but rather hard. No method, however, is employed to soften it. There are hardly any wells in the town, and those that have been found are closed on the ground that they contain foul water. The supply is equal to 6 000 000 gallons per week, and the water rate is not high—about 13s. on a rateable value of £48. This brings in about £4000 a year, and of this a good half is net profit. Formerly there used to be taps over the water-closets, and these were often left running all night. Then the water-supply would fall short, and the sewer air entered the pipes. A large number of inspectors had to be appointed. They succeeded in preventing this waste, and the town was able to give a constant supply to all the houses.

When the borough was extended a very considerable increase of rain-flow was taken into the main sewer that runs inland up the valley. Here there is a great deal of subsoil water, which even in dry weather half fills the main sewer, and is useful in diluting the sewage and in flushing the sewer. But the surface rain water is in a great measure drained into a stream that passes through the centre of the town. The rainfall from the back yards and the back portion of the roofs of the houses goes into the sewer; but the rain water from the streets and the front roofs is conveyed by surface-drains to the stream. The worst and most difficult part of the drainage of Dover is that of the streets running parallel with the beach. From the corner of East Cliff to Hawkesbury-street, where the pumping station is situated, the distance is 5300 feet. The East Cliff corner is 25.5 feet above the Ordnance Datum, and Hawkesbury-street 14.3 feet. Indeed, throughout the central part of Dover a fall of scarcely more than 10 feet can be

obtained. Here some alterations will have to be effected. Self-cleansing sewers cannot be obtained under such conditions. As it is there are often small floods in and about the pumping station. But it is probable that all the houses in this neighbourhood will be pulled down and replaced by docks when the harbour works are more advanced. The abolition or the raising of this district will, however, make the fall of the sewers even less than it is at present. Thus an important, a radical alteration for the drainage of a portion of the town will become necessary. Works which were commenced shortly after 1848 can scarcely be expected to meet modern exigencies and the requirements of the very great increase of population which has taken place since that time. It will, however, remain to the lasting honour of Dover that this town was among the first to lead the way in effecting those reforms that have so materially contributed to reduce the death-rate of the towns of England.

THE CONGRESS OF MEDICINE IN MUNICH.

(Continued from p. 950.)

April 2nd.

THE THERAPEUTIC ACTION OF FERRUGINOUS COMPOUNDS.

PROFESSOR BUNGE (Basle), having referred to the importance of the part played by hæmoglobin in the animal economy, said that it is very improbable that iron in the form of inorganic salts introduced into the human body by the food becomes converted into hæmoglobin by synthesis. The case is otherwise with organic ferruginous combinations such as are present in the yolk of egg in the form of nucleo-albumins, from which the hæmatogen originates. Several combinations of iron exist in milk and also in vegetables, the latter containing a considerable amount, but milk only a small quantity. This seems to be incompatible with the fact that milk contains all the elements necessary for the growth of a young organism; but this deficiency is compensated in young animals by a very large reserve stock of iron derived from the placental circulation, and when this stock is exhausted they instinctively begin to take vegetable food. The same is the case in the human subject. The iron necessary for her offspring has been in process of accumulation by the mother not only during her pregnancy but ever since her arrival at puberty. Perhaps the appearance of chlorosis is caused by the fact that the solid tissues of a woman abstract iron from the blood without giving anything in return. This compensation can only be effected by means of organic preparations of iron, which alone are absorbed; whether they are assimilated is very doubtful, and, therefore, the best way to provide the human body with the necessary amount of iron is by the dietetic use of ferruginous vegetable products. Ferruginous drugs only act by suggestion—the iron which is to be assimilated must be obtained from the market-garden, and not from the pharmacy.

Professor Quincke (Kiel) stated that he had made investigations as to the quantity of free iron in the tissues, and had found that it increases or decreases according to the chemical qualities of the ferruginous preparations ingested. According to him there are three varieties of iron compounds present in the human body: (1) that in the tissues; (2) the reserve stock; (3) that in the circulation. Ferruginous preparations he divides into six classes: (1) ferrocyanic combinations, which have no influence on the organism; (2) blood, which is usually held in reserve, but may be usefully given in anæmia; (3) diluted hæmoglobin; (4) citrate of iron, which does not coagulate albumen; (5) insoluble combinations, which, if subcutaneously injected, are in course of time absorbed; (6) the other oxides and suboxides of iron. These form albuminates in the stomach and intestines, and are but slightly absorbed in the normal body; perhaps more so in anæmia, where they became directly assimilated. He is persuaded of the efficacy of ferruginous preparations, especially of the suboxides and albuminates; but is not of opinion that organic compounds are preferable to inorganic, the inorganic iron being changed in the intestines into an organic combination. Sufficient experiments have not yet been made on the therapeutical value of hæmoglobin. He finally remarked that drugs cannot be dispensed with in the treatment of chlorosis.

Dr. Heubner (Berlin) said that infants ought not to be fed too long upon milk.

Dr. Siegfried (Rippoldsau) thought that ferruginous medi-

cines in conjunction with residence in mountainous localities would be successful.

Dr. Zimmermann (Basle) did not agree with Professor Bunge's opinion that the quantity of iron in the food was sufficient, and thought that suitable iron preparations were therefore necessary.

Dr. Nothnagel (Vienna) advised chlorotic patients to stay some weeks in bed at the beginning of the treatment.

Dr. Edlefsen (Hamburg) recommended the administration of hydrochloric acid with iron preparations.

Dr. Ewald (Berlin) thought that this combination should be used only when the gastric hydrochloric acid was ascertained to be deficient.

April 3rd.

THE DEBATE ON THE ANTITOXIN TREATMENT OF DIPHTHERIA. — (Continued.)

Dr. Treupel (Freiburg) reported that he had made injections of 200, 600, 1000, and 1500 antitoxin units on rabbits and dogs. Their general state, the temperature, the respiration, and the blood pressure remained normal; skin eruptions or changes at the places of injection were not observed. In the urine there was for some time after the injection a small quantity of albumen, but no microscopical elements, such as casts. It is probable that the albumen in the urine consists of albumose or peptone. It is doubtful whether albuminuria is a constant symptom after the injections, whether it is special to antitoxin, or whether it depends merely on the injection of blood serum in general.

Dr. Siegert (Strasburg) had concluded from his experiments: (1) that the injection of antitoxin produces albuminuria, diminution of the quantity of urine, and increase of its specific gravity, these symptoms being more aggravated when the kidney is irritated; (2) that the injection of carbolic acid causes no albuminuria, but an increase of the diuresis and of the specific gravity; (3) that an injection of carbolic acid diminishes the effect of antitoxin; (4) that an intravenous injection of 10 cubic centimetres of antitoxin No. II. is very well tolerated by healthy rabbits; (5) that a subcutaneous injection of defibrinised horse serum kills a rabbit in from two to four days, the changes in the urine being the same as after antitoxin injections; (6) that a subcutaneous injection of 10 cubic centimetres horse serum with carbolic acid produces the same changes, but the animals do not die. Dr. Siegert declared that he was far from asserting that these results would be repeated in the case of the human subject.

Dr. Vierordt (Heidelberg) was not of opinion that the course of the fever in diphtheria, as suggested by Dr. Heubner, has anything characteristic. He ranked himself among those medical men who reserve their judgment as to Behring's methods.

At this point the discussion was closed, and Dr. Heubner's motion, given at the end of the report of the first sitting, was adopted.

April 4th.

THE PATHOLOGY AND TREATMENT OF TYPHLITIS.

Professor Sahli (Berne) described typhlitis and perityphlitis as inflammations which arise from the interior of the intestine and in course of time attack the walls of the cæcum, the vermiform appendix, and the surrounding tissues. This infection is caused by the presence of pyogenic bacteria in the cæcum. The marked swelling in perityphlitis results from an infiltration of the tissues round the cæcum, the vermiform appendix, the peritoneum, the omentum, and the fascia transversalis. This swelling becomes still more increased by the accumulation of faeces. Every case of typhlitis with palpable swelling is attended by suppuration, but these cases nevertheless often recover, the pus partly being absorbed and partly finding its way spontaneously into the interior of the bowel. The disease at the outset should be treated by opiates and absolute rest, together with total abstinence from food. When there is no improvement within three days an operation becomes necessary. An immediate operation should only be performed if the patient suffers from continuous fever, if he is seized with shivering, and if the temperature and the pain suddenly increase after an apparently favourable initial stage of the disease. To avoid relapses the vermiform appendix must be removed, even if the pus is spontaneously evacuated into the intestines.

Professor Helferich (Greifswald) said that the presence of pyogenic bacteria produces purulent catarrh of the mucous membrane of the cæcum; and if the mucous membrane is abraded by the passage of faeces the resulting suppuration

easily penetrates through its walls. As soon as the symptoms of suppuration—fever, pain, and sweating—are recognised an operation should be performed. It would be wrong to wait till the abscess becomes palpable or to rely on the possibility of spontaneous cure. Above all, the symptoms of approaching perforation of the peritoneum should be attentively observed. Appendicitis, of course, is often present without any grave symptoms and only becomes manifest by a sudden aggravation of the patient's general state.

Dr. Sonnenburg (Berlin) made a distinction between simple and purulent appendicitis. The former he has observed in twelve cases post mortem; it is characterised by the absence of all grave symptoms affecting the temperature and the pulse, and by a short and mild course. These cases should be treated expectantly. Purulent appendicitis, which begins with shivering, vomiting, diarrhoea, severe pains, &c., should be operated on. Where the abscess has opened through the intestine the vermiform appendix must be removed.

Dr. Curschmann (Leipzig) stated that in his experience the mortality was at the rate of 5.4 per cent. in 452 cases. He did not agree with Professor Sahli that all cases were purulent. There is also a sero-fibrinous exudation. The swelling in perityphlitis often arises from accumulation of faeces, sometimes also from a matting together of the infiltrated tissues. He declined to give general rules for operating, for in this disease it is essential to take into consideration the circumstances of each case.

Dr. Aufrecht (Magdeburg) said that cases should be distinguished according to the site of the exudation. The disease is less dangerous when the exudation is merely extra-peritoneal, and much more dangerous where there is phlegmonous infiltration of the tissues behind the caecum. In the latter case an immediate operation is necessary, but in the former it is permissible to wait till an abscess results.

Dr. Quincke (Kiel) thought that accumulation of faeces is seldom a cause of real typhlitis. Very often the administration of an enema effectually relieves the patient. This treatment, of course, should only be used when no alarming symptoms are present.

Dr. Augerer (Munich) reported some cases where after a comparatively short time symptoms of grave ileus appeared. The post-mortem examination only showed a small intussusception.

Dr. Sonnenburg remarked that he had also seen cases of this kind. He was of opinion that these symptoms arise from an autointoxication of the body by bacteria.

Dr. Heubner (Berlin) stated that in such cases even a very early operation had not succeeded in averting the death of the patients.

April 5th.

SUBCUTANEOUS NUTRITION.

Dr. Leube (Würzburg) said that for this method of nutrition only fatty substances are suitable. In order to show that fat is really absorbed and assimilated Dr. Leube injected fifty grammes of butter under the skin of emaciated dogs. After the injection fat was once more found to be present in the subcutaneous tissues and in the internal organs of the animals. Chemically it proved to be partly the natural fat of the dog and partly butter. When the animals were kept without food it again disappeared, so that it had evidently been consumed like the natural fat of the body.

THE ABSORBENT POWER OF THE RECTUM.

Dr. Posner (Berlin) reported that he had injected solutions of aniline colours into the rectum of rabbits, and that in from twelve to fifteen minutes they were totally absorbed. This fact should make physicians very cautious in giving drugs by the rectum.

Dr. von Ziemssen and Dr. Riper agreed with Dr. Posner. Dr. von Noorden recommended the administration of quinine by the rectum in whooping-cough.

OTHER PAPERS.

At the final sitting Dr. Rumpf (Hamburg) read a paper on the treatment of Enteric Fever by injections of cultures of the bacillus pyocyaneus. His experiments were of course made on animals only.

Dr. Taoma (Magdeburg) made some observations on the Elastic Tissue of the Arterial Walls and on Angeliomalacia.

Dr. Noorden described a new means for the early diagnosis of Diabetes Mellitus. He administers glycoside to patients who either from natural or hereditary predisposition are suspected to suffer from diabetes, and if this substance appears in the urine the case must be treated as diabetic.

Dr. Ott spoke on Nucleo-albumins.

Dr. Dehio (Dorpat) discussed Cardiac Myofibroma and its clinical symptoms.

Many other papers were also read before the Congress, which exigencies of space compel us reluctantly to leave unrecorded in our columns.

The arrangements made for the comfort of the visitors were excellent, and the reception on behalf of the profession of Munich was very cordial. It was a subject of general remark that a very great number of visitors came not only from the German Empire, but also from Austria, Switzerland, the Russian Baltic provinces, and other countries where German is spoken.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the water-supply of the Parish of Lympham, by Mr. T. W. THOMPSON.—This inquiry was undertaken owing to a complaint by the county council of Somerset to the effect that the then existing rural sanitary authority of Axbridge had failed to provide the parish of Lympham with a proper water-supply. The parish is a scattered one. The water-supply is derived from certain wells, and also to a large extent from ponds, ditches, &c.; and so scarce or bad is it at times and in certain places that some people send out of the district for a supply which is brought in by water-carts. Of the wells Mr. Thompson says that they are of a generally unsatisfactory character; they contain mere surface water, and they are situated in such proximity to drains, privies, cesspools, and highly polluted ditches that they cannot fail to become contaminated. Even the so-called parish well is situated in a grass field which is occasionally manured, and it has within about ten yards of it an offensive and almost stagnant ditch, into which a privy and the drainage of a cottage discharge. It would be bad enough if the Lympham people were content with such water for their own consumption and purposes, but they palm it off on others and make money out of the transaction. Thus dairy-farming is the principal local industry; milk is largely produced there, and it is either distributed to large towns or made into cheese. Everyone knows how large a share water-supply has to do with such operations, and it is well, as far as Lympham is concerned, that it should also be known that even where Lympham dairy farmers take the trouble to send elsewhere for their drinking-water, and thus evidently admit the unfitness of their local supply for dietetic purposes, they were found to be using that local supply for "dairy operations," including a so-called cleansing of milk-vessels. In one case cans were "cleansed" with water from a dry-steined well alongside a pig-yard. But perhaps the most unsatisfactory circumstance in this Lympham inquiry is the weak attitude adopted by the now happily defunct rural sanitary authority, who, having had several schemes of water-supply under consideration, and having informed the Local Government Board that one scheme had been found not only the least expensive, but the most feasible, practically say that because the parish have rejected it they dare not proceed unless the scheme is "ordered to be carried out." We can only hope that the new district council will hold a higher view as to its duties, and that in the evidence before them they will take away the reproach of Lympham and of those of its inhabitants who imagine that a water-supply which is subject to the constant risk of very filthy pollutions is good enough for a parish which thrives on transmitting dairy products to neighbouring populations, and does not hesitate to use such water in the various operations necessary to the preparation of those products.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Whitechapel Urban Sanitary District.—The condition as regards nationality of a considerable proportion of Whitechapel may be judged by Mr. J. Loane's remark that "a stranger coming into some of the streets of Spitalfields might be excused for doubting that he was in the capital of England at all"; and it appears from Mr. Loane's current report that in 1894, 1046 foreigners were added to the Whitechapel population. The birth-rate of the district was a high

one—i.e., 40·3 per 1000, as against a rate for the whole metropolis of 30 per 1000. The general death-rate for the district was in 1894 20·3 per 1000, that in the model dwellings was 18·3 per 1000, and the zymotic death-rate in the same buildings 3·8 per 1000. Mr. Loane states that he finds considerable difficulty in carrying out the provisions of the Housing of the Working Classes Act, 1890; the magistrates, he thinks, do not exhibit any sympathy towards the Act in question. Mr. Loane's report embraces the reply of the Whitechapel Sanitary Committee to Dr. Hamer's report on the sanitary condition of Whitechapel, and we are glad to see that the sanitary authority have decided to add two more inspectors to their staff.

Salisbury by the Sea Urban Sanitary Authority.—Dr. W. W. Stainthorpe, in his current report for the district, records an interesting, and in a certain degree an amusing, conflict of interests which took place between his sanitary authority and the Cleveland Water Company. This company issued notices to a large number of its customers ordering that the water waste preventers flushing the waterclosets should be so reduced in capacity as to supply only two gallons of water to each flush. The sanitary authority, being advised of the insufficiency of two gallons, endeavoured to persuade the water company to rescind their order, and waited as a deputation upon the company. The directors, however, refused to repeal their order, and the sanitary authority thereupon issued a circular intimating to the water consumers that, inasmuch as the water company declined to allow a sufficient flush, it was desirable that the consumers should flush their closets *before* as well as *after* use. We are afraid that this alternative will hardly be equivalent, from the point of view of utility, to the three-gallon flush after use, but possibly it may have the effect of bringing about a compromise with the company. At all events, this is a further illustration, if such be needed, of the undesirability of water-supplies being in the hands of companies instead of sanitary authorities.

Carlisle Urban Sanitary District.—Mr. William Brown, in his last annual report, states that among the prosecutions instituted during the year for the exposure of food unfit for consumption was one having reference to two salmon affected with a salmon fungus (*saprolegnia ferax*). The defence set up by the defendant was based in the main upon a statement contained in the twenty-first annual report of the inspector of salmon fisheries that "the salmon disease appears to be a purely cutaneous affection, and the fish appear to die partly from irritation and consequent exhaustion and partly perhaps from the drain on their resources caused by the production of so large a mass of vegetable matter at their expense. The flesh of a diseased salmon, however extensive the morbid affection may be, presents no difference in texture or colour from that of a healthy fish, and those who have made the experiment declare that the flavour of a diseased fish is as good as a healthy one." As it appears that both the condemned salmon had numerous "discharging surfaces" on various parts of their bodies we are glad to see that no one else was allowed to make a further experiment and that the defendant was heavily fined.

St. Ives Urban Sanitary Authority.—Mr. J. M. Nicholls' annual report for 1894 indicates that some progress has been made in the sanitary condition of St. Ives during the year. Among the improvements either accomplished or in progress may be mentioned a new scheme for draining the town, a better system of scavenging, a new water-supply, and the adoption of modern by-laws. We note, however, that the scavenging is entrusted to a contractor, and that the district possesses neither an isolation hospital nor a disinfecting apparatus. Mr. Nicholls, in referring to the Adoptive Acts, apparently includes among them the Dairies, Cowsteds, and Milkshops Order. We may point out, as we have done on several other occasions, that the Order is in no sense adoptive, but that its provisions are obligatory upon all sanitary authorities. Perhaps, however, Mr. Nicholls is referring to the adoption of regulations under Section 13 of the Order.

Maldon Rural Sanitary District.—Dr. Thresh records, in his 1894 report for this district, two cases of diphtheria in which the evidence pointed to a cat as the source of infection. The two patients were seen to be nursing a cat in a dying condition, and two or three days later both were attacked with diphtheria. Unfortunately the cat was killed and buried before any opportunity of a bacteriological examination offered itself. Dr. Thresh, in the report before us, reminds the Maldon rural sanitary authority that the sewage

outfall of Burnham is near the oyster beds, and that the sewage is discharged into the river without filtration or treatment of any kind. Dr. Thresh expresses the opinion that there is danger in discharging crude typhoid-infected sewage near the beds in which oysters are fattening. Out of nine cases of typhoid fever notified from the Maldon rural district during 1894 no less than seven occurred at Burnham. Out of the seven cases referred to, two were oyster diedgermen, one was a night watchman on the oyster beds below the sewage outfall, and one was a nightsoil driver working at Shoeburyness.

Waltham Holy Cross Urban Sanitary District.—Mr. J. Damer Priest suggests in his report the desirability of making by-laws in regard to the keeping of poultry, rabbits, &c., in confined backyards. The water-supply of the district seems to be far from satisfactory, a large number of wells in it being polluted. The mains of the East London Water Company are, it seems, laid in almost every street, and it would appear that the sanitary authority which preceded the present district council were far from energetic in carrying out the provisions of the Public Health Act, 1875, in the matter of water-supply. Doubtless the new council will rapidly make up for the apathy of their predecessors.

Newton Abbot Rural Sanitary Authority.—Mr. W. Harvey supplies in his report on this district an account of the outbreak of water-borne typhoid fever which occurred in Lustleigh in 1894. The house in which the first case, an imported one, was treated was a detached one situated in a large garden traversed by a mountain stream supplying cottagers lower down with water. The stream in question became specifically polluted, probably by waste water in which infected linen had been washed, and conveyed the disease to the cottagers drawing their supplies from the stream. Curiously enough, the people in the cottages below the first infected house complained that the water of the stream had an odour of carbolic acid. The sanitary authority had not, it appears, been without due warning of the danger to which this unprotected stream was liable, as a few years ago an outbreak of diarrhoea, described as almost of choleraic intensity, occurred in the same row of cottages as that now in question, and had its origin in the same water-supply. Wiser counsels have at last prevailed, and the stream has now been piped. There will, Mr. Harvey remarks, be no more epidemics from this cause.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6105 births and 4160 deaths were registered during the week ending April 13th. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 35·0 to 23·4 per 1000, further fell last week to 20·5. In London the rate was 19·3 per 1000, while it averaged 21·4 in the thirty-two provincial towns. The lowest rates in these towns were 14·0 in Swansea, 14·1 in Croydon, 16·1 in Portsmouth, 17·3 in Huddersfield, and 17·8 in Halifax; the highest rates were 24·6 in Manchester, 24·9 in Wolverhampton, 25·5 in Birmingham, 26·7 in Bolton, and 28·2 in Preston. The 4160 deaths included 330 which were referred to the principal zymotic diseases, against 314 and 274 in the two preceding weeks; of these, 103 resulted from whooping-cough, 68 from measles, 57 from diphtheria, 50 from diarrhoea, 26 from scarlet fever, 20 from "fever" (principally enteric), and one from small-pox. No fatal case of any of these diseases occurred last week in Wolverhampton, Derby, Huddersfield, and Gateshead; in the other towns they caused the lowest death-rates in Hull and Sunderland, and the highest rates in Cardiff, Blackburn, Plymouth, and Manchester. The greatest mortality from measles occurred in West Ham, Plymouth, Bolton, and Manchester; and from whooping-cough in Brighton, Liverpool, Manchester, Salford, Oldham, and Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the thirty-three towns. The 57 deaths from diphtheria included 27 in London, 5 in West Ham, 5 in Cardiff, and 2 each in Manchester, Salford, and Leeds. One fatal case of small-pox was registered last week in Birmingham, but not one in London or in any other of the thirty-three great towns. There were 47 small-pox patients under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 13th inst., against 58, 55, and 13 at the end

of the three preceding weeks; 9 new cases were admitted during the week, against 14, 11, and 7 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1463, against 1587, 1555, and 1519 on the three preceding Saturdays; 117 new cases were admitted during the week, against 184, 161, and 143 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 1448 to 427 in the six preceding weeks, further fell to 398 last week, and were 10 below the corrected average. The causes of 61, or 1.5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Bolton, Oldham, Preston, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Bradford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the six preceding weeks from 42.8 to 24.7 per 1000, was again 24.7 last week, and was 4.2 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 20.6 in Perth and 21.1 in Edinburgh to 26.1 in Paisley and 31.1 in Aberdeen. The 714 deaths in these towns included 30 which were referred to measles, 30 to whooping-cough, 15 to diarrhoea, 6 to scarlet fever, 4 to "fever," 3 to diphtheria, and not one to small-pox. In all, 88 deaths resulted from these principal zymotic diseases, against 90 and 74 in the two preceding weeks. These 88 deaths were equal to an annual rate of 3.0 per 1000, which exceeded by 1.4 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 56, 35, and 22 in the three preceding weeks, rose again to 30 last week, of which 10 occurred in Edinburgh, 8 in Leith, and 6 in Aberdeen. The deaths referred to whooping-cough, which had been 26 and 25 in the two preceding weeks, increased to 30 last week, and included 20 in Glasgow and 3 in Greenock. The 6 fatal cases of scarlet fever exceeded the number recorded in any recent week, and included 5 in Glasgow. The deaths referred to different forms of "fever," which had been 3 in each of the two preceding weeks, were 4 last week, of which 3 occurred in Glasgow. The fatal cases of diphtheria, which had declined from 9 to 2 in the three preceding weeks, were 3 last week, all of which were registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 199 and 189 in the two preceding weeks, further declined to 161 last week, but were 54 above the number in the corresponding period of last year. The causes of 52, or more than 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 48.6 and 43.3 per 1000 in the two preceding weeks, further declined to 29.2 during the week ending April 13th. During the thirteen weeks of last quarter the death-rate in the city averaged 37.1 per 1000, the rate during the same period being 26.0 in London and 30.5 in Edinburgh. The 196 deaths registered in Dublin during the week under notice showed a decline of 94 from the number in the preceding week, and included 6 which were referred to the principal zymotic diseases, against 12 and 11 in the two preceding weeks; of these, 2 resulted from "fever," 2 from small-pox, 1 from diarrhoea, 1 from whooping-cough, and not one either from measles, scarlet fever, or diphtheria. These 6 deaths were equal to an annual rate of 0.9 per 1000, the zymotic death-rate during the same period being 1.6 in London and 2.7 in Edinburgh. The fatal cases of small-pox, which had been 5, 1, and 3 in the three preceding weeks, were 2 last week. The deaths referred to different forms of "fever," which had been 2, 4, and 1 in the three preceding weeks, were 2 last week. The mortality from whooping-cough and from diarrhoea showed a decline from that recorded in recent weeks. The 196 deaths registered in Dublin last week included 30 of infants under one year of age, and 74 of persons aged upwards of sixty years; the deaths both of

infants and of elderly persons showed a marked decline from the high numbers in recent weeks. Three inquest cases and 3 deaths from violence were registered; and 75, or more than a third, of the deaths occurred in public institutions. The causes of 14, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

A VACANCY will shortly occur in the Principal Medical Officership at Devonport by the retirement of Surgeon-Colonel F. H. Welch. Brigade-Surgeon-Lieutenant-Colonel Riordan has been appointed Principal Medical Officer at Cork in succession to Surgeon-Colonel Maunsell, transferred to Bombay. Surgeon-Captain Forde has been transferred from York to Dublin. Surgeon-Captain Morris has been posted to Cork and Surgeon-Captain Elliot to Belfast. Brigade-Surgeon-Lieutenant-Colonel Boileau, Surgeon-Major Loughheed, and Surgeon-Captain Freeman have been granted sick leave from India. The following Surgeon-Lieutenants have been posted to the stations named: Harrison, Chester; Howell, Hounslow; Lawson, Portsmouth; Steel, Chatham; Profeit, Edinburgh; Kiddle, Devonport; Stadden, Whitehead, Perry, Heaton, and Morison, Ireland; Tomlinson, Dover. Surgeon-Colonel Churchill has embarked for Madras.

ARMY MEDICAL STAFF.

Surgeon-Captain John Francis Bateson, M.B., from the Seconded List, to be Surgeon-Captain, vice J. H. Daly, placed on temporary half-pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following are appointed the Principal Medical Officers of the four commands:—Punjab: Surgeon-Colonel R. Harvey, at present Inspector-General of Civil Hospitals. He has proceeded home owing to ill-health. Bengal: Surgeon-Major-General T. Walsh, A.M.S., at present Principal Medical Officer, Madras Army. Madras: Surgeon-Colonel C. E. McVittie (Madras), at present Principal Medical Officer, Southern District. Bombay: Surgeon-Major-General J. Warren, A.M.S., as at present. Surgeon-Colonel G. C. Ross, Administrative Medical Officer and Sanitary Commissioner, Central provinces, is appointed Inspector-General of Civil Hospitals, Bengal. Surgeon-Captain C. J. Sarkies is appointed to the Medical Charge of the Baroda Residency in addition to his duties as Medical Officer, 8th Regiment Bombay Infantry. Brigade-Surgeon-Lieutenant-Colonel W. F. Burnett, A.M.S., is appointed to officiate as Principal Medical Officer, Madras District. Surgeon-Major A. Keogh is directed to proceed from Madras to Barrackpore for duty. Surgeon-Major C. B. Maitland assumes Medical Charge of the 1st Bombay Lancers at Neemuch. Surgeon-Captain A. Stables proceeds in Medical Charge of the 1st Battalion East Lancashire Regiment, moving on Field Service.

NAVAL MEDICAL SERVICE.

Fleet-Surgeons Robert William Williams and William Graham are placed on the Retired List at their own request.

The following appointments are notified:—Fleet-Surgeon W. Graham to the *Thunderer* for service in Pembroke Dockyard. Staff-Surgeons: J. E. Penn to the *Derestation*; G. F. Wales to the *Wildfire* for the *Sans Pareil*. Surgeons: E. J. Morley to the *Pique*; C. H. Upham to Plymouth Hospital; P. H. Boyden, M.B., to the *Thunderer*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain James Walker Beattie, M.B., 1st Durham Volunteer Artillery (Western Division, Royal Artillery) to be Surgeon-Captain.

YEOMANRY CAVALRY.

Suffolk (the Duke of York's Own Loyal Suffolk Hussars): Surgeon-Captain R. H. Lucas resigns his commission; Henry Charrington Martin, M.D., to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion, the Suffolk Regiment: Surgeon-Major J. S. Holden, M.D., to be Surgeon-Lieutenant-Colonel. 2nd Volunteer Battalion, the Prince of Wales's Own (West Yorkshire Regiment): Surgeon-Captain S. Johnston, M.D., to be Surgeon-Major. 1st Volunteer Battalion, the Royal Welsh Fusiliers: Llewelyn Frederick Cox, Gent., formerly Lieutenant, to be Surgeon-Lieutenant. 4th Volunteer

Battalion, the East Surrey Regiment: Surgeon-Captain E. J. Lawless to be Surgeon-Major.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Surgeon-Lieutenant H. W. G. Macleod, M.B., to be Surgeon-Captain.

THE CHITRAL EXPEDITION.

Our daily contemporaries have kept our readers fully acquainted with the rapid progress of events in connexion with this expedition, which has been conducted with great ardour and heroic energy, and promises to have a dramatic ending. People in this country can have but a faint idea of the almost insurmountable obstacles and difficulties of a campaign of this nature. The march of Sir Robert Low's force has so far been a very arduous one; the natural obstacles have made strong demands upon its physical energies and engineering skill, to say nothing of the opposition from hostile tribesmen. The Malakand, Kotgala, and Kamrani passes have been traversed and the Swat river crossed, and a number of other difficult passes and physical obstacles have still to be encountered and overcome before the march to Chitral has been accomplished. Meanwhile another portion of the Relief Expedition—the troops from Gilgit—under Colonel Kelly and Captain Borrodalle, in spite of the intense cold, violent snowstorms, and numerous cases of frost-bite and snow blindness, have succeeded in a brilliant march and military undertaking by advancing over the Shandar Pass, which is 12,000 ft. high and some ten miles distant from a peak of an altitude of 21,000 ft. The enemy was encountered and defeated near Gasht, our garrison at Mastuj has been relieved, and Colonel Kelly's force is now probably fast advancing on Chitral itself or has already reached it. The loss of Colonel Batty, who was killed while in command of the Corps of Guides in their fighting retreat towards the broken bridge over the Panjkora, will be deeply regretted. We believe we are correct in saying that no less than three of his brothers had previously lost their lives in the field in Indian warfare. The health of the troops, apart from the cases of frost-bite and snow-blindness to which we have alluded, is understood to be excellent, and the wounded are doing well. From all accounts it would seem that, as Umra Khan's brother is a prisoner, Umra Khan, who is stated to be suing for peace, will himself soon be compelled to yield. There is every prospect of the expedition being soon terminated satisfactorily, but let it end how it may it will prove, we suspect, to have been an enormously expensive one to the Indian Government.

THE VOLUNTEER MEDICAL STAFF CORPS AT NETLEY.

The London companies of the Volunteer Medical Staff Corps arrived at Netley on the evening of April 11th for their annual training at the Royal Victoria Hospital. The advance party arrived on the previous afternoon. The strength was as follows: six officers and 195 non-commissioned officers and men, of whom twenty were bandsmen. One-half of the men present were students of medicine from the various London hospitals. The officers at the training were Surgeon-Lieutenant-Colonel A. T. Norton, V.D., F.R.C.S. (senior surgeon to St. Mary's Hospital), commanding; Surgeon-Captain D. M. O'Callaghan, A.M.S., adjutant; Surgeon-Captains J. E. Squire, T. H. Openshaw (assistant surgeon to the London Hospital), and W. E. Raw, and Lieutenant and Quartermaster Pilling. Between Good Friday and Easter Monday, in addition to ward and sentry duty, the parades, drills, inspections, &c., two lectures were delivered by Brigade-Surgeon-Lieutenant-Colonel Evatt. On Saturday he chose for his subject "The Reason for the Existence of the Volunteer Medical Staff Corps," and on Monday "The Duties of the Medical Staff Corps in the Field," showing the various stages in the transport of the wounded from the fighting line to Netley Hospital. The Volunteers left Netley for London on Monday evening. During the time of the training the weather was very bright, with a north-east wind prevailing. The companies presented a very creditable appearance.

SMALL-POX IN CALCUTTA.

An epidemic of small-pox is prevailing in Calcutta at the present time, and it is stated that no less than 20,000 people have been vaccinated in Calcutta during the past month. Dr. Simpson, the health officer, has applied to the municipality for the use of two houses in addition to the existing accommodation to convert into small-pox hospitals, one for natives to consist of fifty beds, and the other, of twenty beds, for Europeans.

The Queen's Birthday will be celebrated in London alone

on Saturday, May 25th, and at all other stations, naval and military, on the preceding Friday.

Correspondence.

"Audi alteram partem."

"THE WOMEN'S FREE HOSPITAL, SOUTHAMPTON."

To the Editors of THE LANCET.

SIRS.—I had hoped to have been spared the necessity of writing to you on the affairs of the Southampton Free Hospital for Women, but I am compelled to do so by the astonishing statements made with regard to me in the letter addressed to you by the chairman and honorary secretary of the committee of that institution. In this they say: "The committee exceedingly regret having publicly to express their views on this point, but it is necessary to do so. They are of opinion that Dr. Playfair has treated them in a most discourteous manner. He listened to the accusation of the Medical Society. He never communicated with the committee or the staff of the hospital to which his name was attached, and the committee of the Women's Hospital received a letter from the secretary of the Medical Society, to whom Dr. Playfair had written, saying he strongly approved of the proposal of the Medical Society to hold a committee of inquiry."

As an answer to these indictments may I beg you to do me the favour of publishing the following correspondence:—

1.

"31, George-street, Hanover-square, W., Jan. 10th, 1895.

"To the Honorary Secretary of the Southampton Free Hospital for Women.

"SIR,—I have had sent to me a circular signed by the honorary secretaries of the Southampton Medical Society, in which they suggest that a committee of inquiry into the work and management of the Women's Free Hospital should be appointed. Will you do the favour of informing me, as consulting physician to the hospital, whether it is the intention of your committee to agree to this proposal? In my opinion it is one which should at once be carried out. When the work and management of a charitable institution such as yours have been publicly impugned full enquiry should be courted. Nothing could be better for such an institution than a favourable report from a qualified and unbiased committee of investigation. If this proposal is declined the public will naturally come to the conclusion that there is something which it is wished to conceal.

I am, &c.,

"W. S. PLAYFAIR."

2.

"1, Clifton-villas, Hill-lane, Southampton, Jan. 11th, 1895.

"Dr. Playfair, Women's Free Hospital.

"DEAR SIR,—I am in receipt of your letter, which I will lay before my committee. I beg to inform you that a special subcommittee has the question under consideration, who no doubt will acquaint you with the facts of the case.

Yours faithfully,

"H. C. PHILLIPS, Hon. Sec."

The promised communication never reached me, but nearly a month afterwards I learnt from another source that it had been decided not to appoint the committee I had recommended. On this I wrote as follows:—

3.

"31, George-street, Hanover-square, Feb. 9th, 1895.

"To the Hon. Secretary of the Women's Free Hospital.

"SIR,—I understand that your committee has declined to accede to the nomination of an independent committee of inquiry such as I referred to in my letter dated Jan. 10th. Under these circumstances I beg to place in your hands my resignation of the post of consulting physician to your hospital.—I am, faithfully yours,

"W. S. PLAYFAIR."

This correspondence, I think, plainly shows: 1. That it is not the fact that I "never communicated with the committee" of the Women's Free Hospital. 2. That I did not resign my post as consulting physician until after the committee had decided upon not appointing a committee of investigation, as I had urged them to do. When the advice of a consultant is not acted on I do not see what other course is open to him. 3. That my communications were not "most discourteous." 4. That I did not suggest that the "Southampton Medical Society should hold a committee of enquiry," but that one should be appointed which was "unbiased" and "independent." 5. That I have expressed no opinion as to the questions at issue between the Southampton Free Hospital for Women and the Southampton Medical Society.—I am, Sirs, yours faithfully,

W. S. PLAYFAIR.

George-street, Hanover-square, April 13th, 1895.

"COLOUR VISION AND ACCIDENTS."

To the Editors of THE LANCET.

SIR,—The importance of perfect colour vision for mariners and railway servants is unquestioned in the minds of ophthalmic surgeons. It is not so, however, in the minds of railway directors and Board of Trade officials, nor, to some extent it would seem, in the minds of members of the medical profession. It is to these members of the profession that (by the kindness of the Editors of THE LANCET) I would appeal to weigh well the reasons that have induced their ophthalmic brethren to make it a burning question of the day, for unless the profession as a whole are convinced that no colour-blind men should be employed wherever red and green signals have to be interpreted, and where their wrong interpretation may mean loss of life and appalling disaster, it is certain that the lay officials who have the final voice in the matter will be unconvinced. In a recent number of THE LANCET¹ Dr. Gowers, in a letter on "Colour Vision and Accidents," asks a series of questions which should not pass unanswered, although I am not sure whether they are asked inquiringly or doubtingly. "For many years," he says, "keen attention has been paid to this question and examinations instituted. Has any accident during this time been brought home to defect in colour vision?" The reply to this question can be best given by quoting cases supplied by Mr. T. Bickerton.² (Case 1, quoted from the *Shipping and Mercantile Gazette and Lloyd's List*, June 29th, 1881: "The pilot of the *City of Austin*, which was lost in the harbour of Fernandia, Florida, last April, is proved to be colour blind. In this way, it would appear, he mistook the buoys, and his mistake cost the owners 200,000 dollars (£40,000). An examination showed that at a distance of more than six feet he could not distinguish one colour from another. The physicians attribute the defect to an excessive use of tobacco.") Case 2, quoted by the same authority, is recounted in a letter from Messrs. McIntyre and Co., Liverpool shipowners: "Our ship *Corbet Castle* collided in the South Channel, bound from Dundee to Cardiff in 1879, with the *T. H. Ramien*, due, as far as we can now make out, to the colour blindness or short-sightedness of the chief officer."

It is clear, then, that accidents have occurred in consequence of defects in colour vision. Dr. Gowers' next question is, "Has any railway servant, found by Holmgren's test to have defective colour vision, been confronted at night with red and white lights and failed at once to distinguish one from the other and to state correctly which was white and which was red?" I do not know whether I am wrong in supposing that what Dr. Gowers meant to contrast were red and green lights, the signals which are most often confused, and that white was printed by mistake, but this is of little consequence to the argument, as it seems clear that what he means is, Have colour-blind men been taken on to the permanent way and there failed to name correctly the colours of the signals? The reply is again "Yes." Professor Holmgren records the following case in point.³ "A locomotive fireman at one end of a private railroad was examined by the railroad surgeon and declared to be completely colour blind. Nevertheless, he was allowed to continue at his work, and he started out as fireman on the next train. The surgeon at once telegraphed the 'director of traffic,' who was at an intermediate station. The director received the telegram a quarter of an hour before the train was to arrive on which was the fireman. He at once improvised a practical test in this way: he ordered a stationmaster a few miles further on to show the 'stop signal' (a red lantern), contrary to what was customary, on the side of the road the fireman had his place on the engine. He then got on the engine and told the engineer not to notice the false 'stop signal' but keep boldly on, no matter what happened. Thus prepared the train went on. The director warned the fireman to carefully watch the signals on his side, and so the train approached the 'stop signal.' When quite near the director called out, 'Why don't you slow up? Didn't you [to the fireman] see the stop signal?' 'No,' he quietly replied, 'all is clear; the stationmaster has shown the usual white light.' This test was naturally striking and convincing. The consequence was, of course, self-evident. Arrived at the other

end of the road the director had the fireman tested by another railroad surgeon. He naturally also reported the man to be colour blind, and the fireman was dismissed for ever from a locomotive."

The next question Dr. Gowers asks is a similar one applied to sailors: "Has," he asks, "any similar fact been established as to red and green lights in the case of sailors?" The circumstances may be considered on all fours with those of railway men, for the colours used are the same, the lanterns are much the same, and the illumination is usually identical. The colour blindness that would lead to an accident in a railway official would be capable of leading to an accident in a sailor. The reply to the question may be found in two more quotations, again from Mr. Bickerton.⁴ The first is to be found in the annual report of the Supervising Inspector-General of Steamboats to the Secretary of the Treasury, dated Washington, 1880, and reads as follows: "On the night of July 5th, 1875, there was a collision near Norfolk, Virginia, between the steam tug *Lumberman* and the steamship *Isaac Bell*, the former vessel bound to, and the latter from, Norfolk. The accident occurred at about 9 P.M. on an ordinary clear night, under circumstances which until recently seemed more or less mysterious. The master of the steamer and all his officers made oath that at the time the signals were made to the tug the latter was from one to two points on the steamer's starboard bow, and consequently the steamer's green light only was visible to the approaching vessel. Yet the master of the tug, whose statement was unsupported by any other testimony, asserted that the steamer's red light was exhibited, and signaled accordingly. The discrepancy in the statements was so great that many persons uncharitably charged the master of the tug with being intoxicated, although no evidence was ever offered in support of the charge. By this accident ten persons lost their lives. Upon a visual examination of this officer under the rules during the past summer, and during which time there had been no question as to his sight, by the surgeon of the Marine Hospital at Norfolk, he was found to be colour blind, two examinations having been accorded him with an interval of ten days between them." In the second case, although no accident occurred, it sufficiently points the moral to be pertinent to the question:⁵ "The steamer *Neera* was on a voyage from Liverpool to Alexandria. One night, shortly after passing Gibraltar at about 10 30 P.M., I went on the bridge, which was then in charge of the third officer, a man of about forty-five years of age, and who up to that time I had supposed to be a trustworthy officer and competent in every way. I walked up and down the bridge until about 11 P.M., when the third officer and I almost simultaneously saw a light about two points on the starboard bow. I at once saw it was a green light and knew that no action was called for. To my surprise the third officer called out to the man at the wheel, 'Port!' which he was about to do, when I countermanded the order and told him to steady his helm, which he did, and we passed the other steamer safely about half a mile apart. I at once asked the third officer why he had ported his helm to a green light on the starboard bow, but he insisted it was a red light which he had first seen. I tried him repeatedly after this, and although he sometimes gave a correct description of the colour of the light he was as often incorrect, and it was evidently all guesswork. On my return I applied to have him removed from the ship as he was in my opinion quite unfit to have charge of the deck at night, and this application was granted." But supposing we knew of no accidents occurring as the result of colour blindness, it would not prove that they never happen, and we should still be justified in insisting that our trains and our ships should not be officered by colour-blind officials. We may not know of any accidents having occurred through the man who comes round and taps the wheels of the railway carriages being deaf. Yet if we knew that a deaf man were doing the work we should hardly be satisfied if he told us that, although he could not hear the bell note, there was a vibratory thrill which communicated itself to him and told him all was right. We expect the axles to be periodically tested, and we expect that the work shall be done by men who are not handicapped by the loss of any faculty.

In an annotation in THE LANCET⁶ the question is asked whether, because a man is colour blind, it necessarily follows

¹ THE LANCET, March 2nd, 1895.

² Colour Blindness and Defective Eyesight in Officers and Sailors of the Mercantile Marine, 1890, p. 16.

³ Control of Defective Vision on Land and Sea. B. Joy Jeffries, 1883, p. 6.

⁴ Op. cit., p. 16.

⁶ THE LANCET, March 23rd, 1895.

that he cannot tell that there is a difference between a red and a green or be conscious which light is shown. Ordinarily a colour-blind engine-driver can distinguish the signals, not by the colours, but by the difference in the intensity. The obvious meaning of the writer is that as long as the signals can be differentiated it is unfair, or at least unnecessary, to impose more stringent tests. Now, as the colour-blind do not see the colours to which they are blind, it follows that the effect would be the same as changing the coloured signals now in use for white lights and conveying the messages "safety," "danger," and "caution" by turning the light up or down, increasing or diminishing the intensity that is, according to the required signal. Everyone would recognise at once the dangers incidental to signaling by such means; a "bright light," a "medium light," or a "dull light" would be judged not only according to the personal equation of the observer, but also according to the surrounding circumstances. And yet this is how the colour-blind see the colours. On a foggy night, on a snowy evening, or on a misty morning the colour-blind sailor or engine-driver must make due allowances before he can decide whether a light is red or green. His decision depends on a mental process which has to weigh many pros and cons before it can make a deduction. He must enter into an elaborate mental argument with himself whilst travelling at railway speed before he can decide how he shall interpret the signal. The effects of cloud or rain, of fog or smoke, the overshadowing of surrounding trees or buildings, must be duly weighed, even the condition of the lantern itself must be considered before he can decide whether the signal is bright, medium, or dull. All this cerebration must be instantaneous, and it would be a little late when he had ruined valuable rolling stock, to say nothing of its contents (which may be passengers), to find that he had made a slight error.

I am, Sirs, yours faithfully,

W. M. BEAUMONT,

Bath, March 30th, 1895.

Surgeon to the Bath Eye Infirmary.

"WHAT IS 'PREMATURE DISCHARGE' FROM A FEVER HOSPITAL?"

To the Editors of THE LANCET.

SIRS,—In your issue of the 6th inst. you published in the Parliamentary Intelligence the reply of the President of the Local Government Board to questions put to him by the members for Islington on the above subject. In this reply he has been made to state, on information supplied to him by the clerk to the Metropolitan Asylums Board, that there appeared to be no justification for attributing the illness of the father and children to any infection caused by the premature discharge of William Holland from hospital; and that in the case of the two children who had died there was "strict evidence that the disease was diphtheria and not scarlet fever." As I am to some extent responsible for the information on which the members of Parliament based their questions, allow me to say that I hold copies of the death certificates of these children, one of which states that the cause of death was (a) scarlet fever, twelve days, (b) diphtheria, nine days; and the other (a) scarlet fever, (b) nephritis. These children both died in hospital, and, of course, their deaths were certified by the hospital physician. This being so, I entirely fail to discover where the clerk to the Metropolitan Asylums Board obtained his "strict evidence" that the children did not die from scarlet fever, which in each case was the primary certified cause of death, and which was, in the opinion of their private medical attendant, undoubtedly contracted by the too early discharge from hospital of another member of the family suffering from this disease. After all, the question at issue is not, Did these children die from diphtheria? but, Did they suffer from scarlet fever presumably contracted by the premature discharge of William Holland from hospital? I hold that the evidence of the death certificates of the Metropolitan Asylums Board's medical officers is conclusive on this point, and that the children did suffer, as I have alleged, from scarlet fever in the first instance, and that it is impossible for the clerk, in the face of such certificates, to justify the statement for which he has made the President of the Local Government Board responsible.

In your last issue you ask the question, "What is the 'premature discharge' of a patient from hospital?" To this I reply, the return of a patient to his home in an infective condition, irrespectively of the length of time he may have

been under treatment in hospital. I know that at times it is very difficult to state positively that a patient, particularly one who has suffered from scarlet fever, is free from infection. But I hold that in these days of bacteriology it ought to be possible to clear up a doubt as to the condition of a patient before his discharge. Dr. Priestley has recently demonstrated to his entire satisfaction that it is possible by means of treatment with eucalyptus oil so to disinfect patients that they may be discharged with perfect safety to their homes, and he has, in fact, sent a large number of cases of scarlet fever to their homes without having any "return" cases. If to proper and efficient washing and bathing, and cleansing of the mouth and fauces be added the removal of the patients to convalescent wards before final discharge from hospital, then I think there would be fewer return cases than at present. Why the Convalescent Hospital at Winchmore-hill is not more fully used than it is a question I cannot pretend to answer. I hope it is not due to economic reasons, for surely it is the falsest economy to send patients from the acute wards of a hospital to their homes with the almost certainty of conveying with them—it may be in their mouth or throat, or even in their lungs—the poison of the wards which they had just left, for thereby new cases will be created, which of course must entail additional expense for treatment on the parents or on the ratepayers. This subject of the discharge of patients is of the utmost importance to the public, some of whom, I regret to say, have had their faith in hospital isolation much shaken by the recurrence of "return" cases, and I therefore trust that the Metropolitan Asylums Board will endeavour to devise means to prevent the recurrence of any ill results in future.

I am, Sirs, yours faithfully,

ALFRED E. HARRIS,

Islington, April 17th, 1895.

Medical Officer of Health.

To the Editors of THE LANCET.

SIRS,—I have read with much pleasure in THE LANCET of April 13th your interesting annotation, "What is 'Premature Discharge' from a Fever Hospital?" The question is asked, is there not such a thing as recurrent desquamation after an attack of scarlet fever, and may not a patient discharged with a clear skin subsequently in a fresh environment evince a partial redescquamation? I think few of those who have had an extensive experience of this disease have not seen such cases from time to time. It appears to me that the daily antiseptic warm bath so often neglected by the parents after the discharge of the child from the fever hospital would not only act as a preventive in the spread of the disease to others in cases of premature discharge, but also in those of recurrent desquamation.

I am, Sirs, yours faithfully,

C. S. LEE.

"THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED."

To the Editors of THE LANCET.

SIRS,—Your correspondent who signs himself "C. C." must surely be playing a game at figures within himself if he thinks he approaches this momentous question (I use the word momentous advisedly) by gravely stating that £2 17s. on quarter day "is not to be despised." As a matter of fact, the question is one, although it *prima facie* only appears to immediately refer to the above company, who are undoubtedly a most honourable company, and, I venture to state, deal as liberally with their medical officers as their narrow financial margin will permit. The question, however, practically at stake is a very broad one indeed, nor does it refer especially to this company, or any other company or "friendly society," but is simply this: Can nothing be done to put a stop to the abominable system of allowing medical services to be put up to auction by the touters of commercial concerns, and thus having onerous and responsible duties knocked down at an old song? I repeat, this is the broad question at stake. Clearly, medical men are not competent to protect their own private interests, to say nothing of the public, otherwise they would not nibble at the ground bait offered by the commercial world; and even the happy recipient of £2 17s. per quarter would do well to bear in mind that "all is not gold that glitters," and I can tell him, if he will pardon me, that such as he are worth their weight in gold to the commercial world. Now, Sirs, to come exactly to the point, and we need not clog our

heads with figures, as we simply have to stand face to face with one or two very patent facts to solve this question once for all, which, if I shall not shock your correspondents, I will state in broad Saxon-English, even at the sacrifice of all literary refinement. One of these is that as a profession we have to live; (2) somebody must keep us; (3) the aristocracy cannot do so, as their minority is so insignificant that they cannot even keep West-end consultants; (4) the upper middle-class cannot keep us, as they stand likewise in too small a minority, and even these nowadays are for the most part as poor as church mice. It follows, therefore, that the remuneration of our profession, be it little or nothing, must in the aggregate, so far as concerns general practitioners, proceed from the lower middle and working classes, and it is precisely upon the former of these classes more especially that commercial men are playing irreparable havoc. This is sufficiently proved in provincial towns, where private practice has suffered a deficit which it would be absurd to contend has met its equivalent in the remuneration to the medical officers of friendly societies, and although the managing director of the London and Manchester Industrial Assurance Company states without "hesitation" that their officers gain as much from their members as they would regarding those members as private patients, the system, I submit, is to all intents and purposes, so far as the interests of our profession are concerned, one and the same, and that is of touting the public and offering medical services up to auction as aforesaid. In conclusion, Sirs, be it observed if these classes are to have incessantly dinned into their ears by the itinerant touters of enterprising companies the doctrine that a spirit of thrift, economy, and independence can be maintained on their behalf by these societies on payment of mere nominal fees, we may calculate almost to a dead certainty that another decade or two will complete the insolvency of our profession—that is to say, if it is not already complete.

I am, Sirs, yours faithfully,

CLEMENT H. SERS.

Queen's-road, Peckham, S.E., April 11th, 1895.

To the Editors of THE LANCET.

SIRS,—Your correspondent "C. C.," in THE LANCET of April 13th, writing in defence of the above company, compares it favourably with other clubs—Hearts of Oak, Oddfellows, Rechabites, &c.—and hints at irregular payment by these latter. I may say that these clubs where I live pay quite as much—some, I believe, more—than the London and Manchester. But the object of my writing to you is to draw attention to a point not yet alluded to in your correspondence, certainly not by "C. C.": that there is no comparison whatever between the work required of medical officers by any clubs which admit *women and children of all ages without medical examination*, and clubs, such as those referred to, which are for *men only*, who enter in the prime of life and have all to pass a medical examination. These latter are usually of the true working class (though there are exceptions even in these clubs, exceptions mostly due to rise in life after entrance), and require very much less attention in every way than a club of women and children. Men—working men—usually turn up at the surgery. Women and children in clubs, many of them not of the true working class, usually require to be visited. Children have their teething, convulsions, mumps, measles, scarlet fever, &c. to go through; women their uterine irregularities, climacteric troubles, and many other ailments peculiar to their sex. In short, Sirs, the visiting list of any general practitioner, as is well known to the profession, contains very few men in proportion to women and children.

I am, Sirs, yours faithfully,

April 15th, 1895.

EQUITY,

To the Editors of THE LANCET.

SIRS,—I have been greatly interested in the correspondence that has lately appeared in your columns concerning this society, and you will doubtless consent to publish my contribution. I notice that a good many of the letters are written by medical men who do not belong to the society and are simply writing from hearsay. You will probably admit that reliable evidence from a medical referee of the society is required, and such I am in a position to supply. The expressions "sweating" and "degrading" are freely made use of, but I have not seen anything yet to support the

charge of sweating by this society as being in any way different to the prices obtained for other contract work. The letter of Mr. A. M. Moore is certainly worth perusing, but I cannot understand what kind of a society he had got hold of, and am not surprised that he resigned. The payment of the London and Manchester Society is princely compared to it.

I give the figures for visits paid to members during 1894:

	Visits.	Quarterly payments at 1s. per member.
January	49	£30 6s.
February	49	
March	12	
April	14	£29 5s.
May	32	
June	9	
July	42	£31 3s.
August	26	
September	10	
October	93	£23 3s.
November	45	
December	54	
Total	435	£119 17s.

I have not included in the above two patients who had 40 or 50 visits, and who paid for the attendance at a somewhat reduced fee. The number of bottles of medicine I can only estimate, because I kept no record of them, but I put them down at 1200, which is about the same proportion as in Mr. Moore's list. Let us see how it works out as regards payment for actual work done: 435 visits at 2s. per visit come to £43 10s., leaving £76 7s., or 1527 shillings, for 1200 bottles of medicine. I do a lot of work amongst the poor, and I only wish I could get paid at this rate for all of it. I also give you the figures for the past quarter of this year:—

	1895. Visits.	Quarter salary.
January	117	£31 14s.
February	138	
March	96	
	351	

It must be remembered that the influenza epidemic was raging during these months and it struck down people wholesale in my district. Although this last quarter does not pay, I have no doubt that I shall make up for it in the summer. I may add that the above work was conscientiously done (and not by an assistant) and proper drugs supplied. If it were not so I should have no chance of keeping up the list to its present number. When influenza was about I was very busy, visiting in February between 50 and 70 patients daily. If other medical men would give their experience we could then form some idea if "sweating" exists. Abusing the society without arguing on facts will, I am afraid, not carry conviction to many minds.

Now, with regard to the abuses which undoubtedly do exist—viz., touting, people joining who are in a position to pay proper fees, &c. In my experience these cases form a very small percentage of the whole; they are not countenanced by the head office, and are due to the energetic indiscretion of the agents and collectors. The points to be considered are: Is "medical aid" a system which ought to be encouraged? Does it encourage thrift amongst the working classes? Do we medical men get more money (to put it bluntly) out of that class as a whole by this method than by charging ordinary fees? If these questions can be answered in the affirmative, and in these days when political economy and thrift among the working classes are so much talked about it will require a good deal of evidence to prove a negative, then I submit that the abuses complained of can and ought to be remedied. I have never done any parish work, but I know some friends who do, and from what I have seen of it I have come to the conclusion that I am better paid than the "parish doctor" in proportion to the work. There is another point, with your permission, I should like to say something about, and that is the fees paid by the poor people. I observe that the South-West London Medical Society has passed a resolution condemning the practice of charging fees as low as 1s. 6d. Of course, there is nothing to prevent the members of any society passing any resolution they choose, but if they think that medical men who carry on practice in a poor district ought not to charge low fees, such as 6d. and 1s., I can only say they are absurdly mistaken. I fail to see how a working man with wife and family earning between 20s. and 25s. a week can afford to pay 1s. 6d. for medicine and 2s. 6d. for a visit. The fees must be regulated according to the means of the patient, and it is impossible to lay

down a hard-and-fast rule. It seems a pity that "A General Practitioner" sneers at medical men who charge low fees by using the expression "valuing his services" and "estimating his capabilities at 1½d. per week." It is nonsense to say that we are "degrading the profession" by attending the poor at fees they can afford to pay. I thank God, Sirs, that I am able and willing to do it, for I take it to be impossible to degrade our profession by such noble work as healing the sick and helping the poor. I am afraid some of your correspondents think that the public exists purely for the benefit of the profession; I am inclined to think that the profession exists for the benefit of the public. Although I have spoken as above in favour (in accordance with my experience) of "medical aid," I do not consider myself bound to stick up for it through thick and thin, and am quite open to conviction, though at the same time mere abuse will not affect me.

For obvious reasons I do not desire my name to be published, but enclose my card.

I am, Sirs, yours faithfully,

London, S.W., April 15th, 1895.

ONE INTERESTED.

To the Editors of THE LANCET.

SIRS,—In view of the attacks made on the above association in your columns, I ask permission to offer a few observations on the matter, having acted for more than two years as one of its medical officers.

I may premise my remarks by a concise rehearsal of the articles of my belief on the subject of clubs: I believe the less a medical man has to say to them the better, they being simply a development of trades unionism for the purpose of extorting unjust terms from a profession too incoherent and individually selfish to resist such. Unfortunately, however, one is confronted with the awkward fact that a considerable portion of the population consists of persons either too poor to pay even the lowest medical fees (especially when illness is protracted or work scarce) or too dishonest to pay anyone. Clubs are therefore a necessity—an unpleasant one no doubt, but a satisfactory alternative to bad debts. This being so, the question arises, "What is a reasonable club fee?"

As the London and Manchester Industrial Assurance Company has been pilloried in your columns, it being alleged to be a system of "sweating" medical men, I would challenge those who make these charges to adduce examples of "sick clubs" or benefit societies which pay a higher rate of remuneration than one shilling per quarter per member. This is, I believe, the fee fixed by the Foresters, Oddfellows, and other societies, the medical officers of whom, so far from being ashamed of their connexion with such, are in very many cases careful to note such appointments in the pages of the Medical Register and directories. Sick clubs in connexion with various churches and chapels offer even a smaller remuneration; nevertheless, I find that my medical neighbours are content to act as their medical staff without remonstrance.

Passing from the question of fees I shall now proceed to the charge of "touting." Is it to be understood from the grave charges which have been made that the *modus operandi* of the agents of the London and Manchester Industrial Assurance Company consists in going from door to door, libelling all medical men except their own medical officers, who approve of or connive at such unwarrantable action? I do not for one moment believe that such a charge can be substantiated. Isolated cases of improper solicitation by agents may, and I have no doubt do, occur, nevertheless I believe such to be the exception and not the rule. Further charges against this company are that it is controlled by laymen for their own aggrandisement, and combines life assurance with the providing of medical attendance. Are the Foresters and other benefit societies managed by members of our profession, and do they exist merely for the relief of the sick? No one in their senses would assert such. Before assuming that it is unprofessional for a medical man to accept office from a lay body, it must first be proved that such body either calls on him to perform duties unbecoming a professional man, remunerates him insufficiently, or treats him with a want of courtesy or respect due to the profession in general or himself personally. Another alleged grievance against this association is that when members join such a society they sever their connexion with their old and tried medical adviser. I presume this objection applies with equal force to a great many other medical clubs. Some time since a slate club was formed in my district by a

pseudo-philanthropist. Under the mellowing influence of a "high tea" gratuitously supplied many members were enrolled. Their medical supervision was confided to a medical neighbour admittedly on the ground that he had several "shops" in various parts of the district, and numbers of my patients were thus involuntarily placed in the hands of this shopkeeping member of the profession. I have shown that the fees paid by the London and Manchester Industrial Assurance Company, if small, are equal or in excess of those paid by other societies offering medical assistance to the poor; while, so far from its medical officers being, as one of your correspondents alleges, "in bondage," I most emphatically assert, from my own experience, that they are free from any lay dictation and are treated with the utmost courtesy. So far from discouraging such an undertaking, I believe it to be deserving of support, as it does for us what we appear incapable of doing for ourselves—viz., evolving a scheme by which the really necessitous classes may obtain medical relief on reasonable terms.

I am, Sirs, yours faithfully,

April 11th, 1895.

FAIRPLAY.

To the Editors of THE LANCET.

SIRS,—Let me quote from the *Devon Evening Express* a few words from a report of a recent inquest, which illustrates well the baneful results of "touting" under the "medical aid" system, as mentioned in Mr. A. M. Moore's letter which appeared in THE LANCET of the 13th inst. "The Coroner: Was the child insured?—A.: Yes, sir, from birth; I did so to keep the insurance man away.—Asked to explain the latter statement, witness said the insurance agent kept bothering him to insure the child's life, and he thought the easiest way out of it was to do so. (Laughter.)" There can be no doubt that the touting exists, and the evidence of it, though laughable to the public, has its most serious side for the medical profession.

I am, Sirs, yours faithfully,

Elstow, Exeter, April 8th, 1895.

M.D.

ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—Will you allow me to call attention to the fact that the possible dangers arising from imperfect admixture of chloroform and ether in the A.C.E. compound anæsthetic, so ably demonstrated by Dr. Truman, may be obviated by nebulising the mixture in Oppenheimer's globe inhaler or some similar apparatus; as also that by using nitrous-oxide gas as the atomising agent with ether alone (by preference) you get an ideal anæsthetic, scarcely any cyanosis, speedy insensibility, rapid recovery, and, so far as my experience goes, no sickness?—I am, Sirs, your obedient servant,

CHARLES BELL TAYLOR, M.D.,

Surgeon to the Nottingham and Midland Eye Infirmary.

April, 1895.

ANÆSTHESIA FOR LOWER ANIMALS.

To the Editors of THE LANCET.

SIRS,—Attention was recently drawn to the urgent need there is that all lovers of animals should set their faces against operations being performed upon horses and farm stock without recourse being had to the alleviating influence of anæsthetics. Just as surgery now practised upon the lords of creation has widened its boundaries within the past few decades to an enormous extent, so have operations upon their more lowly fellows—the beasts that perish—been multiplied and been rendered more complicated. In the older days the mere suggestion of chloroforming a horse or a sheep was received with a smile, but owing to the advent of wiser counsels the more enlightened among stock breeders have at the present day adopted chloroform as a routine companion to the red-hot iron or the knife. Mr. John Moore, M.R.C.V.S., of Manchester not long ago communicated a valuable article upon the subject. In it he stigmatises operations done without chloroform as "veritable and revolting acts of cruelty and butchery," and indicates that many veterinary procedures are rendered failures because chloroform is not used. Mr. Fleming, himself a strong believer in the routine employment of chloroform for all save the most trifling of operations, assigns as the causes which prejudice men against its use the supposed difficulty of obtaining and maintaining anæsthesia and the attendant expense. Possibly such reasons

had weight in former days; at present they have none. Methylated chloroform is by no means an expensive luxury, and the admirable apparatus which Krohne and Sesemann make for veterinary use in the stock farm at once renders chloroformisation simple and entails quite a trivial expenditure, as the quantity of the drug required is very small. This apparatus is in principal a large Junker's inhaler, with face-pieces specially designed to meet the requirements of the stock farmer. Nor, as a matter of fact, is even this apparatus necessary; an apparatus constructed from a nosebag answers perfectly well. Horses perhaps require more chloroform than other animals, and the cost in their case is estimated by Mr. Moore at 2d. per head; cattle cost far less. The troublesome stage of excitement which to the inexperienced proves a bugbear can, as Fleming and others have pointed out, be lessened or abrogated by the use of a less diluted vapour during the early stages of the anaesthesia. If "crowded on" at first, little difficulty ensues in the later stages. The danger from overdosage in horses and cattle seems, if the most experienced of our veterinary surgeons are to be trusted, quite minimal. Indeed, it is said you cannot kill a horse by chloroform inhalation. For sheep, which are subjected to most painful mutilations, chloroform can be easily employed. How any humane person can deny these patient dumb things so slight a mitigation to their teleological existence it is difficult to say, unless we admit, with the poet, that "only man is vile." The operation is better performed and fewer hands have to be employed when chloroform is used. For castration of calves also and the "ringing" both of bulls and swine chloroform has been widely used, and has rendered the procedure at once more easy and more scientific. Firing of horses is now, notably in the case of favourite hunters, commonly performed under the anaesthetic, and certainly no man can be called merciful who is not "merciful to his beast" in the matter of chloroform. A further point, and one of no slight importance, is the much better results which follow operations undertaken upon animals which have been chloroformed. In a report before me I find that lambs so treated compared most favourably with those subjected to the barbarous handling in vogue in less enlightened farms, while the same may be said with regard to horses and cattle. The rough-and-tumble butchery of the pre-chloroform era of veterinary surgery has little to commend it when compared with the precise methods and accurate results obtained by scientific exponents of veterinary surgery such as can be arrived at by the aid of chloroform. If owners of horses and farm stock and of pets once realised that chloroform for their animals meant not only immunity from pain, but also ensured better results and less risk of failure or accident, there is no doubt that they would insist upon the use of the anaesthetic, and would see that it was given efficiently and in the best way.

I am, Sirs, yours faithfully,

ANÆSTHETIST.

April 10th, 1895.

FATAL HUMAN GLANDERS FROM A NON-FATAL CASE IN THE HORSE.

To the Editors of THE LANCET.

SIRS,—Mr. Garstang's interesting paper on Glanders¹ is a valuable addition to our knowledge of the causation and treatment of that disease. In it he proves that a non-fatal case of discharge from the nostrils of a horse is capable of producing glanders in the human subject, a fact which, though not unknown, is too often lost sight of by medical practitioners as well as by the public. For that reason the following fatal case may be of interest. On May 26th, 1894, I saw a man in consultation with his usual attendant. He then showed the well-known signs of chronic glanders, and on making inquiries I found that a short time before his attack he had been in charge of a horse that suffered from symptoms of general disease with nasal discharge, from which, however, the animal recovered. The point of infection in our patient was on the upper lip, and the submaxillary and cervical glands became quickly affected, those of other parts of the body being subsequently implicated. The patient was afterwards removed to Cork, where he died with symptoms of pyæmia. Dr. T. G. Atkins of that city saw him before his death, and independently made a similar diagnosis of chronic glanders. A medical man who examined the patient also acknowledged that the attack was one of glanders, but did not think that it could have been con-

tracted in the way I have mentioned, as in his opinion the disease is always fatal in the horse. Mr. Garstang's paper has effectually answered the latter objection, and I briefly allude to the above case as it supports the view so clearly propounded in the article referred to and proves the need for greater care in the handling of horses suffering from any discharge from the nostrils.—I am, Sirs, yours faithfully,

Bandon, April 11th, 1895.

J. J. WELPLY.

THE PREVENTION OF SMALL-POX.

To the Editors of THE LANCET.

SIRS,—Seeing so much in THE LANCET lately as to the etiology and prevention of small-pox, I think a short account of the ideas entertained by the Dyaks of Borneo on the subject, and of the mode of application of them by one of their number, might prove amusing, if not instructive, to some of your readers. In the year 1889, while acting as principal medical officer to the Sarawak Government a case of small-pox occurred among the Sarawak Rangers, a corps composed of Sea Dyaks. The case was isolated, and the whole corps (as I thought) was vaccinated. Three or four, I forget which, other cases occurred, only one of which was confluent, and which proved fatal. I afterwards got the following history of this case from the sergeant-major. The Dyaks believe that a devil presides over each epidemic disease, but are not so smart but that a clever Dyak might trick them. While I was vaccinating he slipped over from the unvaccinated to the vaccinated group without being noticed, and told his companions that in such a crowd the "small-pox devil" would never notice it, but think that he had been vaccinated with the rest. The Dyaks said that the "devil" was sharper than the man; I attributed it to non-vaccination, but the Anti-Vaccination League would probably say it was a mere coincidence.—I am, Sirs, yours truly,

J. WIDMER ROLPH,

Medical Officer, Pahang Corporation, Limited.

Kuantan, Pahang, March 6th, 1895.

"THE TITLE OF 'DOCTOR.'"

To the Editors of THE LANCET.

SIRS,—Dr. Campbell Black infers from my letter more than he has any right to do, and evades my contention. I stated that so far as I had been able to ascertain the title of "Dr." as applied to medical men was a "courtesy" one, on a par with that of "Rev." amongst divines, and that no legal question was involved. I also pointed out that Dr. Black would do better to spend a little money in satisfying himself as to the legal question if still in doubt about it. I am so satisfied on the point that I do not care to do it. I very seldom use the title of "Dr." myself, and have a door-plate inscribed "Physician and Surgeon." If, however, this quibble about a courtesy title is carried much further I shall be inclined to ask whether the M.D. confers the title of Physician without the sanction of one of the Royal Colleges. I believe it used not to do so. The whole squabble appears to me puerile and unworthy. Why cannot Dr. Black and others unite with us in our battle against real abuses, such as that of "medical charities," that of "medical aids," and the general tendency to depreciate and undervalue medical services? Surely this would be better than tilting against windmills, and if Dr. Black will do this I care not whether he calls me "Dr." or "Mr."; but he should not assume a knowledge of the amount of brass in my door-plate from a general statement of opinion on an open subject.

I am, Sirs, your obedient servant.

Loughborough, April 11th, 1895.

J. B. PIKE.

P.S.—I may say that in communications from the Royal College of Physicians of Edinburgh I have repeatedly been addressed as "Dr.," and, knowing the position the College takes on the subject, have written to complain of the indignity, which, however, shows the common custom of using the courtesy title.

"A MODERN IMMORTAL."

To the Editors of THE LANCET.

SIRS,—In an annotation headed "A Modern Immortal," which appeared in THE LANCET of Feb. 9th, 1895, the credit

¹ THE LANCET, March 16th, 1895.

of the discovery of anæsthesia is given to Morton of Massachusetts—"Morton, to whom belonged the immortal honour of having been the first to demonstrate that prolonged anæsthesia could be safely produced by means of ether." It is simply for the sake of justice and truth that I write to declare that there is strong evidence to show that Dr. Crawford W. Long, practising in the town of Jefferson, in the State of Georgia, deserves the credit of having been the discoverer of prolonged anæsthesia by means of ether. His first operation under ether narcosis was done in March, 1842—four years before the time of the supposed discovery by Morton. The facts of the case are well brought out by Dr. Luther B. Grandy,¹ of Atlanta, Va., in an article in the *Virginia Medical Monthly*, October, 1893, by means of which he was forced into a contest with Dr. W. R. Hayden (of viburnum compound fame), who bitterly urged the counterclaim of Morton. As an evidence of the great amount of doubt in regard to Morton's claims of priority there is a white marble monument in Boston (where Morton publicly made known his supposed discovery) which bears the simple inscription: "To the Discoverer of Anæsthesia." Does that show that it is acknowledged, even by the people who saw what was done, that Morton was the discoverer? On the contrary, there stands in Paris a marble statue of Crawford W. Long, an enduring witness to the truth; and the Georgia Legislature will place his statue in the National Gallery of Statues in Washington as a fitting recognition of the immortal greatness of her son. Marion Sims published a piece on the subject in the *Virginia Medical Monthly*, May, 1877, in which it is demonstrated beyond practical doubt that Long is the true "modern immortal." It is in the interest of all science that the truth be known, and that not the slightest deviation from it be allowed; and I hope that in this case the truth will surely prevail. *Fiat justitia, ruat cælum.*

I am, Sirs, yours very sincerely,

Lynchburg, Va., March 13th, 1895.

S. P. PRESTON, M.D.

"PROVISION FOR YOUNG IMBECILES."

To the Editors of THE LANCET.

SIRS,—As a guardian of the poor in a country union I ask to be allowed to say a few words in confirmation of the needs of which Dr. Shattleworth has written. On coming to a country union from the metropolitan district I was astonished to find that no provision was made for idiots or imbeciles beyond the county lunatic asylums for adults. I found idiot children running about in the sick wards of the workhouse without any special care or attempt at training, while in a London union they would at once have been sent off to Darenth. This difference in the mode of treatment between London and the country I am utterly unable to understand; the children can only become worse till they are hopeless and have to be sent to the asylum for adult lunatics. Inquiries at all the county asylums for idiots showed that two or three were willing to take pauper children who were thought to be capable of improvement, and after much trouble I succeeded in getting two sent to the asylum at Star-cross, a journey of great expense, and with accommodation entirely inadequate to the needs of all the southern counties. As the subject has been discussed by Poor-law authorities during many years it is almost incredible that no action has yet been taken; we can only go on stating facts till the county councils are impressed with the need of establishing asylums sufficient for the needs, not only of pauper children, but of others also who by timely training might be saved from becoming life-long burdens on the rates. But in asking for educational asylums I would not limit the demand to the most hopeful of the children in workhouses. I would like to see all idiots and imbeciles removed, for the nurses in those institutions are far too few to be able to take proper care of them, and are already in almost all instances overworked. Let the worst as well as the best among them be removed and classified in an asylum, where each and all could have the best care and not be placed, as I have seen them, in wards with lunatics and adults. I would only add that the opening of many more schools or homes for the feeble-minded, who can hardly be classed with either idiots or imbeciles, is urgently called for, the two or three already existing being utterly inadequate for the number of such to be found in every workhouse and pauper school, and who are

unable to benefit by the instruction given there. I may add that I am convinced the numbers far exceed those given in the recent report of the Local Government Board.

I am, Sirs, yours faithfully,

April 11th, 1895.

LOUISA TWINING.

"THE RESULTS UPON THE TESTICLE OF LIGATURE OR DIVISION OF THE VAS DEFERENS."

To the Editors of THE LANCET.

SIRS,—At the conclusion of his interesting lecture on the above subject, published in THE LANCET of April 13th, Dr. Joseph Griffiths deals briefly with the matter as affecting man, and sums up as follows: "It would hence seem that mere division, ligature, or occlusion of the vas deferens does not lead to atrophy of the seminal tubules; but if in case of division there is, in addition, some damage to the other structures of the cord, destructive changes, followed by atrophy and ultimate disappearance of the seminal cells, are liable to occur." As having a practical bearing upon this question, may I be allowed to call attention to a short communication which I published in THE LANCET of March 7th, 1891, upon "The Effect of the Division of Certain Constituents of the Spermatic Cord" &c. ? In that communication I recorded three cases in which to my knowledge not only the vas deferens but also the spermatic veins and artery, with the other structures which go to complete the formation of what is commonly designated the spermatic cord, had been completely divided without any apparent damaging effect upon the nutrition of the testicle, a condition of things of which, so far as I am aware, no previous mention had been made in surgical literature. From these cases and from some other evidence which had come under my notice I drew the following deduction: "that division of the vas deferens, spermatic veins, and spermatic artery [i.e., practically the whole spermatic cord] is not necessarily followed by sloughing or even by subsequent wasting of the testicle provided that a perfectly aseptic condition of the wound is maintained." At the date of my communication the time which had elapsed since the division of the structures indicated was not, perhaps, sufficient to permit of a reliable prognosis as to the final condition of the testicle in these cases. I have, however, quite recently had an opportunity for examining one of the patients concerned, and found the testicle (more than four years after the division of the cord) of normal size and consistence, and with its peculiar sensation indistinguishable in character and intensity from that of the opposite organ. The fact that I am unaware of any similar instance having been recorded is my main excuse for troubling you with this letter.

I am, Sirs, yours faithfully,

WILLIAM H. BENNETT.

Chesterfield-street, Mayfair, W., April 15th, 1895.

"PULEX IRRITANS."

To the Editors of THE LANCET.

SIRS,—In your annotation in THE LANCET of April 6th regarding the means of destroying this irritating pest one plan not mentioned upon one occasion gave exceptionally good results. The matting of my bungalow in Java suddenly became infected with myriads of fleas, so numerous that the legs, covered only with loose white trousers, were instantly coated with a living mass. Strong quassia tea was freely used as a wash to the mat-covered floors, and the swarms vanished as by magic.—I am, Sirs, yours truly,

April, 1895.

RICHARD NEALE, M.D. Lond.

"ILLEGAL VACCINATION."

To the Editors of THE LANCET.

SIRS,—In the annotation under the above heading in THE LANCET of April 13th you deplore the increase of irregular and inefficient vaccination. That such an increase is a stern reality and fraught with most pernicious consequences must be the experience of every general practitioner, however limited his experience may be. After pointing out the extreme laxity with which the term "successful" is used in its application to vaccination you further add: "The small-pox statistics of the past decade would have presented a different aspect than they

¹ *Virginia Medical Monthly*, October, 1893, February, 1894, March, 1894, and June, 1894.

do had vaccination been carried out by all practitioners with the efficiency demanded by the Local Government Board," and you express a desire for some definite pronouncement on this subject in the forthcoming report of the Royal Commission. Now, if this august body should advocate the abolition of vaccination as a compulsory measure this decision would be held by many to be distinctly condemnatory of the Jennerian theory. But would the enforcement of such a recommendation be of any material detriment to the cause of vaccination? Probably not. In fact, probabilities point in the opposite direction. If vaccination was purely voluntary, the consequences would be that those who submitted to it would do so from a firm belief and conviction in its efficacy as a protective, and with a view to procure the desired result would use their best endeavours to have it performed thoroughly and efficiently, and not in the perfunctory manner in which it is now so often done simply to meet a Parliamentary requirement. Under present circumstances, from the inefficient way in which the operation is often carried out, it is well nigh impossible for the general public to form any just estimate or in any way appreciate the true protective value of vaccination against small-pox, for there are hosts of individuals going about their daily avocations sincerely believing that they are almost absolutely proof against their dreaded foe, and each one of these individuals who is struck down by small-pox is regarded by the general public as a further proof of the uselessness of vaccination because he has been vaccinated and is yet afflicted, whereas in very many cases the operation performed on him was about as efficacious as in ancient days was the assumption of an amulet with mystic rites. It is obvious, then, that the larger the majority of the efficient cases out of the total of those operated on the less must be the difficulty of the public in recognising the true value of vaccination as a protection from small-pox, for they will be unable to point to vaccinated patients among the sufferers. Hence in years to come the more efficient performance of vaccination—and the more efficient because it is voluntary—must lead to a greater prominence of its real merit, and the general public will learn from living object-lessons to believe in a theory which a beneficent Government has failed to establish by legislation.

I am, Sirs, yours faithfully,

Worthing, April 13th, 1895.

W. T. WYATT.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Manchester Chamber of Commerce on Lead Poisoning.

ON JAN. 5th attention was directed to a case of lead poisoning at Newton Heath, where evidence was given at the inquest as to the conditions under which work was carried on. At the meeting of the Chamber of Commerce on the 10th inst. the question of dyeing with chromic lead colours was brought up. The Chemical Sectional Committee laid certain resolutions before the Board, illustrated by a number of sample hanks of yarn which had been dyed by the chairman of the committee—some with chrome lead colours, the rest with other colouring materials—for purposes of comparison. The Board substantially adopted the resolutions of the Sectional Committee as follows: 1. "That the dyeing of goods with chrome lead colours, and especially the handling of goods dyed with these colours, is injurious to the people employed, unless special provisions are made and due precautions taken, and unless the workpeople heartily coöperate in making use of the appliances provided for their protection." 2. "That in view of the fact that the wearing of goods next to the skin coloured wholly or partially with chrome lead dyes under certain conditions may be injurious to health, it is desirable to substitute these dyes by others derived from innocuous colouring matters of similar colouring properties." 3. "That it would be an injustice to the dyeing trade to place any restrictions upon the colouring of goods by chrome lead colours unless such restrictions are also extended at the same time and to the same degree to the importation to this country and its colonies of such coloured goods, also to the dyeing trade of India, in which country very considerable quantities of goods are so dyed, one dyeworks alone being stated to turn out 20,000 lb. of yarn per day dyed with chrome lead colours." 4. "That the attention of merchants and their clients be called to the injurious effect of chrome

lead colouring materials, and to the existence of others less injurious to health, producing similar colour effects, of which there are several." Commenting on this discovery of a fresh Indian trouble the *Manchester Courier* says: "The dyeing of cotton goods with chrome lead colours appears to be fraught with a double share of the evils of lead poisoning." It not only injures the health of the workpeople employed, but "it is capable of slowly poisoning people who wear cloth thus dyed next their skin." These facts have evidently impressed the mind of the Chamber, and "the directors warn merchants and their clients of the baneful influences which lurk in tissues displaying the gaudy colours derived from chrome lead," and call their attention to the existence of other less injurious colouring matters which might be substituted. As the *Manchester Courier* says: "Lancashire manufacturers might be depended on to make the change if the matters rested with them alone." But the compliment is a somewhat doubtful one, for it is equivalent to saying that they would do right if there were no temptation to do wrong. Unluckily, India is a formidable competitor, *ergo* the third resolution, that it would be an injustice to restrict the use of these chrome-lead dyes unless it was done all round; and the paper asks: "What would it profit this country for its merchants to sacrifice the profits of chrome-lead dyeing if Indian and other competitors only took advantage of their conscientiousness to make a greater use of the poisonous colours than ever?" It does not believe the Anglo-Indian Government will "surrender all at once to this challenge of the Manchester Chamber of Commerce on the subject of this free trade in lead-poisoning," so the poor manufacturers, it is to be feared, must let their conscientiousness go. When commercial interests are in conflict with ethics and morals the latter run much risk of defeat; but it is a sorry doctrine that because you poison your neighbour I will do likewise.

A Publican's Responsibilities.

IN MY last communication a conversation was mentioned that took place at an inquest between Mr. Smelt, the deputy coroner, and a jurymen as to supplying drink to a drunken man, in which some strong remarks were made by the former on the responsibility of the publican if the man came to his death as a result. Since then the publican has had to appear at the City Police-court, charged with selling beer to a man already drunk and with permitting drunkenness. According to the evidence the man Flanagan and his wife had some drink together in a beerhouse. The wife then went home, but he adjourned to the defendant's, where he had a further quantity of drink, and by eleven o'clock was very drunk. In spite of this the publican's wife served him with some porter in a bottle, and suggested to another customer, who was also drunk, that he should see Flanagan home. It was stated at the inquest that as the men were going up the steps at the Jersey-street workmen's dwellings Flanagan fell back and received injuries to the head from which he died. At the court the widow said he had suffered from heart disease, and had been upset by the recent death of his father. It was said also that he was a good deal excited at the last public-house he visited, and in the court the story of the fall was somewhat modified, as his guide said he sank down or collapsed instead of falling backwards, as stated at the inquest; but at any rate he fell down the steps and fatally injured his head. The defendant's solicitor contended that heart disease and not drink was the cause of the fall, and that it was the existence of the former that led the landlady to send a man home with him. How she ascertained the condition of his heart is not stated. The publican said he was sober, but nothing seems so difficult for a publican as to make out the diagnosis of drunkenness. The summons was dismissed, the presiding magistrate saying there was a doubt in the case, and they had decided to give the benefit of it to the defendant.

Paupers' Tea.

IN February last the *City News* published a new and improved dietary table which had been prepared for the Salford Workhouse. The weekly cost of food for old men was to be raised from 1s. 6½d. to 1s. 11½d., that of old women from 1s. 4½d. to 1s. 9½d., and of children up to sixteen years of age from 1s. 9½d. to 2s. 3½d. This amounts to an increase of about 20 per cent. on the old expenditure, but, as the editor says, "no one would charge the guardians with extravagance even under the increased scale." In the issue of the 6th inst. it is stated that the improved dietary

does not appear to have come into operation yet, but the guardians are preparing for it "by effecting economies in other directions." It states that one of the new guardians drew attention to the quality of the tea still supplied to inmates, by whom it is said to be irreverently called "munko." It is made in the proportion of one ounce to eleven pints of water. The new guardian, whose taste cannot as yet have been educated up to workhouse tea, says "the compound is unfit to drink," and complains that the guardians have contracted with a retail dealer for tea at twopence a pound less than last year—i.e., at a shilling a pound instead of one and twopence. It seems that the strength of the tea was overstated in February, for instead of eight pints to an ounce nearly eleven pints of water are used. "Three-farthings worth of tea to eleven pints of water!" We are often told of the injurious effects of strong tea, from which, however, the Salford guardians do their best to save their "inmates," being due to the tannin and bitter extractive dissolved up by prolonged infusion. This is apparently disbelieved by the authorities at Withington, one of our largest local workhouses, and one supposed to be under the most scientific and philanthropic management. Here the tea is put into a canvas bag, dropped into the copper or cauldron, and infused—for three minutes or for five so as to get as little tannin as possible? By no means. They want to get all, tannin, extractive, and anything else that will come out, so it is infused for forty minutes! But although at this workhouse an ounce and half are used where Salford uses an ounce, the tea is said to be "very bad"—so bad, indeed, that the old women do not take milk with it, as it would destroy all flavour that might remind them of tea. The ratepayers should be remembered, and no extravagances indulged in by sentimental guardians; but with regard to tea a pitiful economy seems to be used.

The Corporation and Infectious Disease.

Hitherto the treatment of infectious disease in Manchester has been carried on by the Royal Infirmary under an arrangement with the corporation. For many years this plan has worked well, and the infirmary has done much to earn the gratitude of the citizens by the disinterested labour it has gone through in relieving the city of a great responsibility. The recent threatened invasion of cholera, and the serious epidemic of small-pox through which we have passed, made it necessary for the city to provide increased hospital accommodation for infectious disease on a large scale, in addition to that afforded by the infirmary at the Monsall Fever Hospital. These and other circumstances have gradually led to the opinion that it will be best for the city to acquire the hospital from the infirmary, and take charge itself of the treatment of infectious disease. The small-pox epidemic was a costly visitation, for it led to the expenditure by the corporation of £16,706 for new pavilions at Monsall, of £2204 for a temporary hospital at Withington, and of £4668 for a supplementary convalescent home at Clayton. The question of the transfer, though in a nebulous condition at present, is sure to come prominently forward before long, and so also is the necessity for a small-pox hospital at a sufficient distance from population. There has long been a bitter cry from Newton Heath against the treatment of small-pox at Monsall.

April 16th

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

St. Andrews Ambulance Association.

ON April 13th Dr. Alexander Thom's class, which has been conducted under the auspices of the St. Andrews Ambulance Association, along with his ordinary yearly volunteer class, was examined by Dr. Simpson, medical officer of health for Perth. Fifteen candidates presented themselves, six of them being for second examination with a view to obtaining the medallion. All the candidates passed, and the examiner expressed himself as being highly satisfied with the general knowledge displayed and with the acquaintance shown in practical bandaging and stretcher drill. As six of the candidates were constables of police the public may be satisfied that in this part of Scotland at least mistakes are not likely to be made between cases of illness and drunkenness which arrive at the police cells.

Unwholesome Food.

During March 4049 lb. of beef, 43 lb. of mutton, 140 lb.

of "offal," and 757 lb. of fish were seized by the Aberdeen sanitary inspector and destroyed by magistrates' order or with owners' consent as unfit for human food. During the quarter January—March the city analyst, besides examining five genuine samples of butter, one of milk, and four of oatmeal, found two specimens of butter containing 60 per cent. foreign fat, one sample of water "unfit for drinking or cooking," one specimen of milk with "metallic impurity of non-injurious character," one of oatmeal containing 7 per cent. foreign granules, and another containing 3 per cent. foreign granules.

Proposed Memorial of a Donor of Medical Bursaries.

The late Mr. George Thompson of Pitmedden presented to the University of Aberdeen the sum of £6000 in 1882 to found medical bursaries, and a further sum of £3000 in 1886 to institute a travelling fellowship in medicine. Emeritus Professor Struthers writes from Edinburgh to an Aberdeen newspaper suggesting that a marble bust of Mr. Thompson, or a replica of his portrait in Aberdeen town hall, should be obtained for the hall of the University. In the course of his long career Mr. Thompson was Lord Provost of Aberdeen for three years, and represented that city in Parliament for five years.

The First Instance of Cremation in Scotland.

The remains of Mrs. Elizabeth Haining Laurie were cremated at the Western Necropolis, Maryhill, on Saturday afternoon last, at her special request. This is reported to be the first case of disposal of the dead by burning in Scotland.

A Medical Volunteer Camp.

The 1st Aberdeen Medical Staff Corps, under Surgeon-Captain Macgregor, will go into camp at Birkhall, Ballater, on Thursday, May 30th, and will remain under canvas till the following Monday.

Of 48 candidates 27 have passed the medical preliminary examination at the University of Aberdeen.

April 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Poor-law Guardians in Ireland.

THE *Dublin Journal of Medical Sciences* of this month contains an interesting paper by Dr. Dickson on Women as Poor-law Guardians. It would appear from it that the number of female guardians in England has very greatly increased since a woman was, for the first time, elected at Kensington in 1875. In 1887 there were fifty women guardians, while there are now in England no less than 800. In Ireland we are differently circumstanced, for the Act of Parliament of 1838 relating to the Poor-law administration here contains the distinctive expression "male person." No such phrase is to be found in the English Poor-law Amendment Act of 1834 and accordingly no legal objection to the election of women has ever existed in England. It is interesting to note that women seem to have failed to discover their eligibility in this regard for more than forty years.

Mercer's Hospital, Dublin.

I regret to note the death of Mr. McGuckin, who was long and honourably known as the registrar of this hospital. He was well known to many of the medical profession in Ireland and, indeed, also to the general public, as the father of the eminent tenor, Mr. Barton McGuckin.

Small-pox in Enniscorthy.

An outbreak of small pox has recently occurred in the town of Enniscorthy, the disease having been transferred in all probability from Dublin, for the man in whom it first showed itself had paid a visit to the metropolis exactly twelve days before. Although he remained there but a few hours, during which he drove across the town to return with his wife, a surgical convalescent from a hospital to which small pox is not admitted, he seems to have caught the disease and carried it home with him. Since that date—i.e., during the last five weeks—twenty-four cases have occurred, of which one proved fatal. It is interesting to note that the patient, a child eleven months old who died, was one of five unvaccinated children, all of whom were attacked with the disease in its confluent form, in marked contrast to the mild variety which afflicted the patients who had been vaccinated. The local authorities have made every effort to cope with the disease by revaccination, isolation, &c. The arrangement for the latter proved,

however, quite insufficient, so that it has now become necessary to build special sheds in the neighbourhood of the fever hospital for that purpose.

The Royal College of Surgeons in Ireland.

The council of the Royal College of Surgeons has accepted the gift of a portrait of Mr. Henry Gray Croly, senior surgeon to the City of Dublin Hospital and formerly President of the College. The portrait, which is at present being exhibited at the Royal Hibernian Academy, was presented by the influential committee who organised this testimonial to Mr. Croly.

Intermediate Examination in Natural Science.

A medical man writes a sensible letter to the local daily journals in which he suggests that elementary biology should be included amongst the subjects for examination by the Intermediate Commissioners in 1896. Elementary botany has hitherto been required, but from girls only, while zoology has been altogether omitted. Many of the universities and licensing bodies specify biology as a compulsory subject. It would certainly smooth the path of the medical student who had adopted the programme of the Intermediate Commissioners if elementary biology had been one of the subjects in their curriculum.

The Calamity at Mountstewart.

Not alone in the north but in every part of Ireland regret has been felt at the calamity in Strangford Lough, by which eight lives have been lost. These, with the exception of two boatmen, were all trusted servants of Lord and Lady Londonderry at Mountstewart House, and persons of experience and character, whose loss will doubtless be much felt. The empty boat has been found, but up to this, the 16th inst., none of its occupants or anything to account for the disaster.

The Battle of the Clubs at Cork.

One grievance the Cork club medical officers complained of was that for a miserable pittance they are obliged to attend not only the club member, but also his family, the latter often including grown-up sons earning quite as much as their father. Not alone that, but the clubs generally regarded all persons dependent on the member as part of his family, and the practitioner was often called on to prescribe for uncles, aunts, and even mothers-in-law. However, I am glad to find that one of the imported medical men is not in sympathy with such a liberal widening of the family circle, and he has adopted what I am sure will prove a very effective method of defining what shall be the smallest amount of work he need do for his equally small remuneration. On being recently called to visit a club member's brother he went without demur, but on the completion of the attendance he very much surprised the member by furnishing him with a bill for medical services rendered. The member was so much unaccustomed to that sort of thing that he actually lodged a complaint against the medical officer at the next meeting of the club. He received abundance of sympathy from his brother members, but some of the more prudent told him that under present circumstances they could not think of fighting with their medical officer. Possibly the hint will not be lost on the other imported medical men, and the clubs may learn before long that certain disadvantages are likely to accrue from the attempt to procure medical services at ridiculously low prices.

The Cork Ophthalmic Hospital.

I have already mentioned that considerable friction exists with regard to the selection of a site for the new buildings. Engineers have given opinions for and against the position which had been all but decided on. The general committee were naturally perplexed, but their difficulties were still further increased by finding that the ladies' committee were waging a newspaper war amongst themselves. Lady Arnott, whose name was prominently identified with the recent successful bazaar, opposed the adoption of the proposed site, and referred to the large sum of money she had been instrumental in collecting. Other members of the ladies' committee promptly replied that Lady Arnott had done good service as treasurer, but that the heat and burden of the day had fallen to the lot of some seventy or eighty lady collectors. The net result of the controversy has been that other sites are under consideration. Lady Arnott has resigned, and the general committee have requested her to withdraw her resignation.

The Conjoint Board of the Irish College of Surgeons and Apothecaries' Hall, Dublin.

Dr. Edward Townsend, Professor of Practice of Medicine

at the Cork Queen's College, has been appointed Examiner to the joint board of the Irish College of Surgeons and the Apothecaries' Hall, Dublin. Comparatively few of the Cork students become candidates for that qualification, but those of them who may present themselves for the examination will, I am sure, be glad to find a professor from their own college amongst the examiners.

The County Kerry Infirmary.

Dr. W. B. Hayes of Tralee has been unanimously appointed surgeon to the County Kerry Infirmary. Dr. Hayes studied in Cork and Dublin, and obtained his degrees at the Royal University of Ireland. He afterwards went to San Francisco, where he enjoyed a lucrative practice, but was obliged to return home owing to the ill-health of his father, Dr. J. Hayes, a highly esteemed practitioner in Tralee and coroner for the district. Dr. Hayes' appointment to the Infirmary is certain to give general satisfaction in the neighbourhood.

The Hospital for Children, Temple-street, Dublin.

Dr. M. C. Staunton and Mr. J. Lentaigue have been appointed surgeons to this hospital.

April 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Anti-streptococcus Serum.

On the 23rd ult. M. Marmorek introduced to the notice of the Société de Biologie the important discovery of a serum which appears to be endowed with curative and prophylactic properties *vis-à-vis* of the diseases caused by the streptococcus. It was found that when that micro-organism was passed many times through the system of the rabbit its virulence was greatly augmented, a culture introduced subcutaneously killing a rabbit in thirty hours with a dose of 0.000,000,000,01 c.c. This exceptionally active microbe retains its virulence in cultures and generates a toxine of vastly greater power than had been prepared up to that date. Previously immunised animals inoculated with this powerful microbe and those which receive a strong dose of the toxine it generates furnish a serum which is preventive and curative in its action. Rabbits which have a few hours before inoculation received a dose of this serum resist the action of the poisonous streptococcus above mentioned. Moreover, the inoculation of the culture may precede the administration of the dose of serum with the same result—survival. M. Roger stated at the same meeting that M. Charrin and himself had vaccinated rabbits and then a horse against the streptococcus, and found that the injection of the serum of these vaccinated animals conferred a certain immunity against the action of the streptococcus. A woman affected with puerperal fever, whose temperature had oscillated around 39°C. for a week, and whose condition was most serious, was given an injection of 8 c.c. of the serum without benefit. The next day double the quantity was injected, and on the third day 25 c.c. were given; on the fourth day the temperature had fallen to normal and remained so, the woman quickly recovering. Another puerperal case, also in M. Charrin's wards, but of a milder type than the first, was similarly cured. What struck MM. Roger and Charrin more particularly was the prompt improvement in the general condition and the sensation of *bien-être* experienced a few hours after the injection. It was noticed also that, contrary to the rule in puerperal septicæmia, the period of convalescence was extremely short in duration, the patients being out of bed in five or six days. MM. Roger and Charrin extended their researches into the region of another disease caused by the same micro-organism—viz., erysipelas. We know that erysipelas, when affecting the adult, is capricious in its evolution, but generally ends in recovery. In the newborn, however, erysipelas is almost invariably fatal. The above-named observers (MM. Roger and Charrin) have recently¹ had the opportunity of treating a case of the kind in the person of a weakly infant weighing 2600 grammes, and reared in an incubator in the special pavilion attached to M. Budin's wards at the Maternité. Recovery ensued in a few days. During the illness the weight of the child had fallen from 2780 grammes to 2600 grammes. Weight was, however, quickly gained, no less than 400 grammes being put on in thirteen days. The method has also been tried on a woman aged twenty-five years, who, twenty days after her confinement,

¹ Société de Biologie, March 30th.

was attacked by pseudo-membranous sore-throat, complicating measles. Bacteriological examination revealed the presence in the secretion of the streptococcus and the staphylococcus. The woman was well in a few days. The serum appears to be quite destitute of toxic properties, for no untoward symptoms were noted during the treatment. M. Marmorek further reports² that he has, in conjunction with Dr. Chantemesse, applied the method to the treatment of forty-six cases of erysipelas. All ended in recovery, excepting in some case in which death was accidental. Twenty-four hours after an injection of 10 c.c. the temperature had fallen, and complete recovery occurred in forty-eight hours. It is stated that this treatment prevents albuminuria consecutive to erysipelas, and that when present the serum treatment promptly effects its disappearance. The profession will await with eager curiosity the further developments of the application of this new arm directed against the inroads of that mischievous germ, the streptococcus. Should M. Roger's hopeful anticipations be realised serotherapy will have made one more step in advance, and suffering humanity will have good reason to be thankful to such ardent workers as Richet and Héricourt, Charrin and Marmorek, and especially to Roger himself, who can claim the credit of the discovery.

The Purification of Filters.

Dr. Guinochet, Pharmacien-en-chef of the Charité Hospital, Paris, has recently indicated the precautions necessary for the continued efficient working of filters, and more especially of the Chamberland-Pasteur apparatus. In the case of ordinary filters the *bougies* must be unmounted, well brushed, and rinsed in cold water, and then plunged, totally if possible—but total submersion is not necessary—for a liberal quarter of an hour in a 1 in 1000 solution of permanganate of potassium. The *bougie* is then removed from the solution, well shaken, and finally rinsed once more in cold water and replaced in the filtering apparatus. The water that filters through the *bougie* is at first coloured, but after a few minutes' working it becomes quite clear, and can be utilised for drinking purposes. This method of sterilisation may be employed for porcelain, stone, or asbestos filters, and is said to be as efficient as it is simple, the permanganate sterilising in the cold every part of the filter. Beyond this it cleanses the porcelain *bougies* by oxidising the glutinous organic matter which chokes the pores. The small quantity of the permanganate that may remain after the sterilising process is over in the pores of the filter is in nowise hurtful to health. But whatever method of sterilisation may be employed the flow is gradually lessened. Dr. Guinochet finds that if after the permanganate process (using this time a 5 per 1000 solution) the same manœuvre be repeated with a 1 in 20 solution of bisulphite of sodium the normal flow was restored. The bisulphite solution is prepared by adding 50 c.c. of a solution (density 1.300) of the commercial salt to 950 c.c. of water. It is as well to add to this solution each time it is used for this purpose 5 c.c. of ordinary HCl per litre. A Chamberland-Pasteur filter may be permanently kept microbe-free by (1) a daily superficial scrubbing with a brush; (2) a weekly (or bi-weekly, if the water to be filtered be very impure) sterilisation with a cold 1 in 1000 permanganate solution; (3) a trimestrial and thorough cleansing with, first, a 5 in 1000 permanganate solution, and then a 1 in 20 bisulphite solution.

A Protest by Hospital Surgeons.

Acting in direct opposition to the Commission de Surveillance of the Assistance Publique, the Prefect of the Seine has, at the instigation of Dr. Seyron (Director of the Assistance Publique), signed the following new regulations: (a) Paris is henceforth divided into hospital districts. A patient cannot in future be received into any other than the hospital of the district in which he resides. (b) The out-patient departments are transferred from the hospital physicians and surgeons and confided to young practitioners who have completed their term of service as *internes*. These regulations, which have not even been submitted for the approval of the Conseil Supérieur of the Assistance Publique, have raised quite a storm, and elicited a lively written protest signed by every hospital surgeon in Paris. The signatories contend that the restriction of the right of the poor hospital patient to choose the establishment wherein, and the surgeon by whom, he may desire to

be treated is a violation of a liberty which every poor man has a right to enjoy. They point out that certain surgeons gain celebrity for certain operations, and they regard the new territorial system as an arbitrary measure *vis-à-vis* of the poor man, who should have as much right as the rich man to choose his own surgeon or hospital. With regard to the dissociation of hospital surgeons and the out-patient rooms, the signatories question if the substitution of young and inexperienced practitioners for themselves will benefit the poor applicants. They maintain that in selecting for admission into their wards the more acute and operable cases they are acting quite reasonably. As for the *chronics*, they say that it is for the Assistance Publique to provide for their hospitalisation and not for them (the surgeons) to encumber their wards with sufferers who may lie therein for months unbenefited. In conclusion, the signatories complain that their advice was never asked in the matter, and they wash their hands of the consequences that are bound to result from the application of what they characterise as a mischievous innovation.

Le Banquet de l'Internat.

This annual function will take place at the Hôtel Terminus on the 20th inst. The *internes* of the Paris hospitals—in other words, the *élite* of the students of the Faculty—will gather to dine under the genial presidency of the ever-popular Professor Tillaux, who will doubtless receive a warm reception from his young friends.

April 16th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Puncture of the Spinal Canal.

At one of the last sittings of the Berlin Medical Society Professor Fürbringer read a paper on Puncture of the Spinal Subarachnoid Cavity. This operation is performed both for diagnostic and for curative purposes. The puncture is made through the ligaments of the third and fourth lumbar vertebral arch by means of a rather small trocar with a long cannula. The fluid must not be aspirated, but must be allowed to flow freely through the cannula. The pain of the operation is sometimes rather severe, but totally disappears after a short time. Professor Fürbringer has made punctures in eighty-six patients more than 100 times without any ill effect. By this means the bacillus of tuberculosis was found in thirty of the thirty-seven cases of tuberculous meningitis, where the diagnosis was doubtful. In twenty-seven of these cases the diagnosis was verified by necropsy. He is therefore of opinion that this operation will become of the same value for the diagnosis of tuberculosis as the microscopical examination of sputum or exploratory punctures of the pleural or peritoneal cavities. In one case of acute idiopathic cerebro-spinal meningitis the presence of pus was recognised. In one case of acute meningitis, for which no obvious cause could be found, the fluid contained an enormous mass of bacteria which appeared to be identical with the pneumococcus. In all cases of increased cerebral pressure the pain was relieved, but only for a short time; in particular, four patients suffering from cerebral tumours felt better after the operation. Professor Fürbringer's results were confirmed by Professor Fränkel, Professor Heubner, and others. Dr. Freyhan said that the proportion of albumen in the fluid obtained by puncture could be easily ascertained. This, he asserted, was of great diagnostic importance, as the proportion of albumen was always greater in cases of meningitis and cerebral tumour than under normal conditions. Sugar was never found in the fluid. In cases of cerebral apoplexy where the blood had penetrated into the cerebral ventricles the fluid was found to contain a large amount of blood; there was much less blood in cases of subdural hæmatoma, and none at all in epidural hæmatoma.

The German Medical Press Union.

A Union of the Medical Press was formed at the last meeting of the German Association, and its rules are now published in the medical journals. Its aims are to raise the position and increase the influence of the medical press and to support its interests on every occasion, especially at medical congresses and meetings. To this end the union makes a claim to be represented on the committees of congresses and to exercise an

² Ibid.

influence on their organisation. It also intends to facilitate the work of the press by appointing special union reporters at the medical societies and providing the journals belonging to the union with these reports. It will also join in protecting the general interests of the profession and the press against encroachments on the part of the authorities and the public. Editors of medical journals which have been in existence for at least two years are eligible for membership. During 1895 the seat of the union will be in Berlin, Professor Eulenburg (*Deutsche Medicinische Wochenschrift*) acting as chairman, and Professor Posner (*Berliner Klinische Wochenschrift*) as secretary. The editors of all the important medical journals have already joined the union.

The Cycle as an Ambulance Carriage.

A new ambulance carriage has been invented by Dr. Hönig of Berlin. It is not drawn by horses or men in the ordinary way, but is propelled by cyclists and consists of a kind of litter resting on a frame with five wheels, three in front in the form of an ordinary tricycle, and two at the back. The drivers accordingly sit one at each end of the litter, which is covered by a removable roof with little windows and a pneumatic bell, so that the patient can communicate with the drivers. Beneath the litter are boxes for dressing materials, instruments for first aid, &c. Dr. Hönig suggests that his invention would be useful in small towns for which a horse ambulance is too expensive. It brings the surgeon and his assistant very quickly to the scene of an accident and enables them to remove the patient to the hospital without loss of time. The general opinion here is that the new system will require a greater proficiency in the art of cycling than the majority of medical men possess. The carriage was shown in the drill-ground of the fire brigade to surgeons attached to hospitals and the police, as well as to officers of police and the fire brigades, and to other gentlemen connected with the ambulance service.

The late Professor Lothar von Meyer.

Lothar von Meyer, Professor of Chemistry at the University of Tübingen, died in that town on April 12th. Although he was not a medical man his name will ever be connected with medical science, and especially with physiological chemistry. He was the first to prove the action of hæmoglobin in the function of respiration, its affinity for oxygen and for carbon monoxide (CO). He also made valuable researches on the poisonous effects of carbon monoxide. Latterly he abandoned medical chemistry and devoted himself exclusively to theoretical chemistry. He was born in 1830 in Varel (Oldenburg) and became successively *privat-docent* in Breslau, Professor in Göttingen, and Professor in Tübingen.

March 15th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Professor Celli on Bathing.

Is it as well known in the British Isles as it is on the Continent that an English physician is the originator of sea-bathing? It is a fact that not before 1750, when Dr. Richard Russell published his treatise on the virtues of sea water (or, to give it its full title, "*De Tabæ Glandulari et de Usu Aquæ Mariæ in Morbis Glandularum*") were the healing virtues of the sea-bath understood or the practice of sea-bathing generally resorted to. Till then there seems to have been a horror of the sea; and, indeed, we know that in mediæval times a compulsory dip in its waters was a sentence often passed on the public offender. In the earlier decades of last century Western Europe suffered heavily under "king's evil," the popular name for that tuberculous affection which scourged all classes, from peer to peasant. Dr. Russell, a Sussex practitioner, had observed that dwellers on the coast, guided by instinct apparently, used to drink of the sea water, bathe in it, even wash their sores in it, and bind them up with seaweed. Having noted the practice long enough to be satisfied of its efficacy, this medical man did not wait for a chemical or physiological theory of its *modus operandi*, but began to prescribe it to his patients with the best results. His treatise, mentioned above, diffused his experience among his contemporaries, so that silently but steadily the English coasts became dotted with villas and cottages, the nucleus hamlets

which, from their sea-bathing advantages, grew into towns. By the close of the century Germany had adopted the practice, then Belgium, and then France, one of whose physicians, Dr. Lefrançois of Dieppe, in 1812 wrote a book on the virtues, internal and external, of sea water, and raised his native town into a much-frequented health resort. From bathing in the sea bathing in fresh water came to be more largely indulged in, till Dr. Andrew Combe's "*Principles of Physiology applied to the Conservation of Health*" (Edinburgh, 1834) set forth with fascinating clearness the vital importance of the skin as a great waste pipe, and the practice of "tubbing" became general in the British Isles, whence it has slowly found its way into the more refined classes abroad. True, this latter was a revival of the ancient Roman use of the bath, which had long lapsed into desuetude; but it was a revival on sound physiological principles, to which it owes the almost fanatical rigour with which it is maintained in all well-ordered British households. Wherever available, in suitable weather the running stream is justly preferred to the bath from the pipe, and all over Europe the great rivers are being more and more utilised for what is at once a hygienically valuable and physically pleasurable exercise. These and a host of cognate facts and considerations were all *en évidence* before the distinguished audience addressed the other evening by Dr. Angelo Celli, Professor of Hygiene in our university, whose participation some five years ago in the International Congress of Hygiene and Demography held in London reflected so favourably on the Roman school. But the point to which he drew the attention of his hearers with most insistence was the quality of the river water in which bathing is practised, the principles it contains in solution, even the solids that it carries down with it from the soil through which it flows. The Tiber, he showed, has chemical properties which explain its health-giving advantages for the bathers in it—the sand to which it owes its colour, transported from Tuscany and deposited by floods along its banks, having a distinctly antagonistic effect on the "*bacteri malarici*"—so much so, indeed, as to make its course "*una vera zona coibente*" (a true restrictive zone) against the poison. Statistics were adduced to demonstrate that the health of the Tiberine population, even where the river flows through malarious tracts, is better than that of the people who occupy regions unhaunted by the fever. Its wealth in carbonates and salines gives it an exceptional advantage over its sister streams, rendering it, as a bathing medium, more akin to the sea than any other Italian river. Its very density is, *per se*, another of its virtues, and brings it nearer the mud bath than most of its rivals having an equally swift and steady flow. Swimming under such conditions, especially in sultry weather when the relaxation of the pores admits of a freer action on and through the skin, is, he contended, one of the most beneficial exercises open to youth, of which the exceptionally favoured students of Rome were, he was glad to think, ever ready to avail themselves. The address, coming from a practical physiologist and scientific sanitarian like Professor Celli, carried conviction to an audience in which the lay as well as the professional public was largely represented, and his colleague, Professor Postemski, who holds the chair of Clinical Surgery in the University, was but the spokesman of all present in thanking the lecturer for his vindication of the Tiber as a bathing ground—a vindication, be it added, not more effective than opportune. A distribution of prizes followed for the greatest proficiency in swimming, and the names of the winners afforded gratifying proof that the health-giving pastime is not incompatible with the steadiest application to university work, whether in the class-room or the clinical ward.

April 16th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Effect of Cold on Diphtheria Antitoxin.

ALTHOUGH in a temperate climate the question of the effect which low degrees of temperature have upon diphtheria antitoxin may not appear one of great practical importance, it is very distinctly so in a country like Russia, where for half the year the thermometer hovers about the Fahrenheit zero, and where, consequently, packets of the

serum sent through the post may be exposed to excessive variations of temperature. Two observers have published the results of experiments undertaken to test the effect of cold upon the serum, particularly with regard to its antitoxic properties. It is impossible to quote the details of these experiments here. The results were as follows. Dr. Gorianski, working in the Imperial (Oldenburg) Institute of Experimental Medicine in St. Petersburg, concluded that "serum which has undergone prolonged exposure to low temperatures loses part of its anti-diphtheritic properties. This loss is considerable, for a quantity of serum one and a half times greater than the maximum dose was unable to neutralise a minimum fatal quantity of diphtheria toxin." In these experiments the serum was exposed to temperatures varying from +29° to -4° F. Dr. Rojanski, on the other hand, whose experiments were done in Professor Filatof's laboratory at the Children's Clinique in Moscow, came to quite different conclusions. He found no difference between serum which had been exposed to cold and that which had not. "From certain experiments," he writes, "it might even be concluded that serum which has been exposed to cold has stronger antitoxic properties than that which has not." He is careful, however, not to commit himself to this conclusion. The discrepancies between his own and Dr. Gorianski's results he attributes to individual differences in susceptibility to the diphtheria poison in the guinea-pigs experimented on. It should be added that Dr. Gorianski used Behring's serum, and that this became cloudy after exposure to cold; while Dr. Rojanski used serum prepared by Dr. Gabritchevski in the Moscow Bacteriological Institute, and this remained throughout quite clear.

The Perm Zemstvo Asylum Case.

A particularly bad case of ill-treatment of asylum patients by their attendants recently came to light in the town of Perm, the capital of one of the most easterly governments of Russia in Europe. It is satisfactory to be able to add that exemplary punishments have been meted out to the offenders. The incidents occurred in the Asylum of the Perm Zemstvo. The superintendent, an army *feldscher* named Mymin, on the night of Feb. 26th (during Carnival week) sent out for a magnum of *vodka*, which he and five ward attendants proceeded to drink. During the night a patient who had been making a noise was struck by one of the attendants; the patient struck back, and a fight followed, in which the four other attendants and two other patients joined. The attendants, who were probably intoxicated, beat the three patients so severely that two of them subsequently died. The superintendent, though awakened, refused to interfere. The court before which the case has been tried has inflicted the following sentences: the attendants are to undergo four years' imprisonment with hard labour, and the superintendent is condemned to exile to Siberia, with deprivation of all rights.

Trional, Chloralose, and Somnal as Hypnotics.

Dr. Kbmielefski of Odessa published in a recent number of the *Meditzinsko Obozrenie* an instructive article upon the relative value of trional, chloralose, and somnal as hypnotics. He found that in asylum practice trional is a fairly certain and rapid sleep producer, but that it is contra-indicated in melancholia, hypochondriasis, or whenever any mental depression is present. It should be exhibited in 1 gramme doses, which may subsequently be increased. Chloralose is somewhat less certain in its action; the amount required to produce sleep varies much in different cases and at different times in the same person. It acts more rapidly than trional, but the sleep is less prolonged. In doses larger than 0.5 gramme slight symptoms of poisoning (spasms, &c.) frequently appear, but they soon pass away, and need not cause alarm. It never causes headache or other unpleasant after-effects which sometimes follow the use of trional. It may be given in cases where trional is contra-indicated, as in melancholia, hypochondriasis and psychoses accompanied by depression. If there is any gastro-intestinal disorder chloralose is, it is stated, almost the only hypnotic which can be given for a prolonged period without harm. Somnal was found in the few cases in which it was given to be a valuable and reliable drug. It produced sleep indistinguishable from natural sleep. In some respects it possesses advantages over trional or chloralose. It is, however, contra-indicated if any gastro-intestinal disturbance be present, as it tends to increase this.

April 14th

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Insuring the Lives of Children.

IN the discussion of a Bill before the Massachusetts Legislature prohibiting insurance companies from writing policies upon the lives of children under ten years of age, in that child-insurance is an incentive to crimes, a member of the Society for the Prevention of Cruelty to Children said that she had found families where the children were deprived of the most ordinary necessities of life, while the money for the insurance of a dying child was set aside awaiting the call of the agent. She knew of a case where the money received for the death of a child was spent on unnecessary display at the funeral, and she could not induce the parents to divert a cent of it to the purchase of food for other children who were suffering for the want of it and were receiving charity. She also told of a mother who, while one child lay dead, was lamenting that two younger ones and her phthisical husband had not been taken instead, because they were all insured and were not wage-earners, while the dead one was. A girl fourteen years of age, so emaciated that the witness could span any part of her arm with the fingers of one hand, was taken away by the society from her parents to prevent them from starving her to death, and it was subsequently learned that her life was insured, and the witness believed she was being murdered to secure the insurance money. This system results in children being deprived of the necessities of life to secure money at their death. They are thus compelled to pay for their own funerals. Who was benefited by such an insurance investment? Not the child, for it is half starved during its brief life, and can receive nothing when it is dead. Not the parents, for after depriving them of the necessities of life they get nothing but a white coffin and a hearse. But it is the insurance companies that make large sums of money for themselves and agents out of this method of extorting money from the poorest classes of people. On the part of the insurance companies it is represented that the mortality among insured children is less than among those who are not insured, that the average policy upon the life of a child less than ten years old is not more than would pay the expenses incident to a funeral, and that people from all classes in all parts of the country take advantage of the system.

The Growth of the Camphor Tree in California.

There is an effort being made to grow the camphor tree in California, which gives some hope of the transference of the world's commerce in that gum from Formosa to the United States. Camphor sold twenty years ago at ten cents a pound, but is now over a dollar a pound, owing to the destruction of trees in Formosa. The report of the United States Department of Agriculture states that the large and increasing quantities of this drug consumed in all civilised countries make the question of its continuous production and regular supply a matter of considerable importance. It is a well-known fact that the sublimation of the crude camphor from the wood is conducted in a primitive, careless way, which causes great waste. The camphor laurels of Formosa are gradually being destroyed under the careless system employed by the Chinese gatherers. In fact, they have been entirely exterminated along the seaboard, and the wood is now obtained from the forests along the frontier, between the settlements of the Chinese and the inland mountainous regions still occupied by the aboriginal population. The camphor gatherers are thus continually exposed to the assaults of the natives, and this interrupts the prosecution of the industry. No attempts are made towards planting other trees to take the place of those destroyed, and a sufficient quantity of the drug is obtained only by constant encroachment upon the territory of the Formosans. This destruction of the trees still further in the interior at every new move gradually exhausts the supply.

Death following the Injection of Antitoxin.

The death of two persons immediately following the injection of so-called antitoxin excites a profound interest in the medical profession. The facts are as follows. A boy from the country while visiting his uncle in Brooklyn developed diphtheria; as he gradually grew worse under treatment the physician obtained a bottle of antitoxin. An injection of this fluid was made, and the boy died

three hours after. On the following day a seventeen-year-old daughter of the uncle complained of a sore-throat. The physician obtained another bottle of the antitoxin, and it was administered. After receiving the injection the girl said she felt a tickling sensation all through her body. She then fell on the lounge in convulsions and was dead in ten minutes, despite the physician's efforts to save her. Her face turned black almost immediately after receiving the fluid. The physician states that the girl's death was a mystery to him, and he could only account for it by crediting it to some powerful poison in the bottle of antitoxin. He had used the remedy for some time with gratifying results, and always got it at the same place. The colour was the same as that he had used, being pink. He had never witnessed such a terrible death. There had been a mistake somewhere in bottling the fluid. The amount injected was between two and three drachms, which came in each bottle. The bottle was put up in a box in Germany, and bears the date of shipment, Jan. 30th last. The necropsy revealed nothing abnormal.

Inspections at Quarantine by Electric Light.

The rules regarding quarantine inspection have heretofore required that they should not be made between sunset and sunrise. This rule often caused great inconvenience to passenger ships. Frequently they would arrive just after sunset in the summer, and the passengers would be compelled to remain on board from eight to twelve hours, often in sight of their homes. The health officer, after consultation with the managers and agents of the principal steamship companies in the transatlantic passenger trade regarding the inspection and clearance of passenger and other vessels at night, conceived the idea of inspecting immigrants by the aid of powerful electric lights. This is to be done by having a detached cluster of burners arranged so that it can be carried on board of a steamer and connected by a switch or other apparatus with the electric lighting system of the steamship. To perfect this arrangement all of that class of ocean-going passenger vessels known as express steamers will be fitted with a connecting arrangement of switches, to permit the connexion of the health officer's cluster of burners. This system will come into effect immediately, and all such steamers will be passed, provided they arrive at quarantine before nine o'clock in the evening. Another important result of this method is the prompt boarding of all vessels subject to quarantine. A man is stationed where he can see the approach of incoming steamers, and it is his duty to give immediate warning of an approaching vessel and the boarding-boat promptly goes towards it. It is not compelled to anchor, but proceeds at slow speed, with sufficient headway to keep steerageway on the vessel.

Powers of Health Boards.

Two persons recently arrived in Brooklyn from places infected with small-pox whom the health board quarantined for observation during the period of incubation. The case was brought into the courts, and the higher court sustained the board. It held that as these persons came from infected places they were liable to communicate the contagion and hence were proper subjects for isolation and detention, which was clearly within the scope, powers, and duties of the board to enforce. The prevention of small-pox is of such paramount importance as to justify all reasonable means for its accomplishment. The propriety and wisdom of the course pursued by the board is beyond criticism; its acts have all been within the lines of statutory authority, and they have been discreet and in evident good faith in the presence of an impending pestilential danger.

March 31st.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Annual Reports of Hospitals.

The annual report of the Sydney Hospital showed the amount of work done at this institution. During 1894, 3266 in-patients were admitted, and the average number of beds occupied was 250, the largest number occupied at one time being 285. Of the admissions, 1401 were urgent cases without any recommendation, 1197 had Government orders and 182 subscribers' orders, while 486 contributed to their maintenance. The percentage of mortality on admissions was 11.8, and of 297 deaths 111 died within twenty-four

hours of admission. In the out-door department there were 113,968 attendances. The directors state that the fact that the expenditure of last year has been kept down to its fullest possible limit, without detriment to the welfare of the patients, is due to the watchful care and economy exercised by the medical superintendent, Mr. George Armstrong. From the balance-sheet it appears that the excess of expenditure over income was £1217. The annual report of the Hospital for Sick Children, Glebe, Sydney, showed that during the year 486 patients had been treated in the general hospital, of whom 389 had been discharged cured or relieved, 16 had been discharged incurable or unrelieved, 33 had died, and on Dec. 31st 50 remained in the institution. In the diphtheria cottage 143 patients had been treated; of these 73 had been discharged cured, 68 had died, and 2 remained in the hospital on Dec. 31st. There had been 1319 patients in the out-door department, with 4256 attendances. The increase in the work of the institution had been remarkable, the cases treated in the general hospital having been one-third as many again, and the out-patients' attendances more than twice as many, as during the previous year. The balance-sheet showed that the patients' payments amounted to £405 17s. 9d. and public donations and subscriptions to £1497 1s. 9d. The expenditure was £4185, of which the sum of £3027 12s. 10d. was for hospital maintenance. The Chairman, Mr. Justice Stephen, in moving the adoption of the report, said that the fears entertained with regard to the establishment of the diphtheria cottage had not been realised, and it was clear that while it benefited the whole community it did not inflict any injury on the inhabitants of Glebe. The medical officer's report showed that during 1894 there had been an increase of 124 admissions over the returns of the previous year. No less than 80 different diseases had been treated, and there had been 50 cases of hip disease, 40 cases of typhoid fever, and 40 cases of pneumonia. Operations requiring the administration of an anæsthetic numbered 300. There had been 143 cases of diphtheria, 73 of which were cured, and 68 patients, or 47.5 per cent., died. Of the 68 deaths 16 or 23.5 per cent., occurred within twenty-four hours after admission. The Government had arranged for regular shipments of diphtheria antitoxin from Germany, and the remedy would be supplied to the hospital. Dr. Tidswell had been appointed Government Bacteriologist, one of whose duties would be the manufacture of antitoxins.

Inquests in Melbourne during 1894.

During the year 1894 381 inquests were held in the city of Melbourne. Of these, 125 were on deaths due to accident, 38 were suicides, 12 by gunshot wounds, 6 by poison, and 6 by hanging. Infanticides numbered 25, a comparative decrease, probably due to the action of the Infant Life Protection Act. Drink was responsible for a large share of the deaths. Of 33 suicides 11 were excessive drinkers, and of the 125 accidental deaths 21 were due to drink. Of those found dead 7 were drinking heavily when last seen alive, 11 died from alcoholic pneumonia, and 8 well-known drunkards died from cerebral hæmorrhage. The total of the "drink cases" was 71. The inquests under the Infant Life Protection Act on infants boarded out numbered 74.

Charge of Malpractice.

Dr. Henry M. Fenwick, of Carlton, Victoria, who was recently committed for trial by a coroner's jury on a charge of manslaughter, was further charged at the Carlton Police-court, in conjunction with two nurses, with performing an illegal operation on two separate occasions. The patients operated on and a nurse who was present gave evidence against Dr. Fenwick, who was committed for trial.

Case of Anthrax.

What is said to have been the first case of anthrax in the human subject in Victoria occurred recently in the person of a stockowner, who had been engaged in inoculating sheep with Pasteur's vaccine against the disease, and while so doing accidentally ran a needle into his hand. Anthrax oedema set in, and the anthrax bacilli were found in the tissues. He was promptly treated with free incisions and the application of pure carbolic acid, and recovered without constitutional symptoms.

Hospital Nurses' Hours of Duty.

A question was recently asked in the Victorian Parliament as to the hours during which nurses in the metropolitan hospitals are on duty, and the Premier replied that from inquiries he found the average was eleven hours per day. This, however, is reckoning from the time they enter the wards till they go to

bed, and includes meal times. At the Melbourne Hospital the actual working hours are about eight and a half. At the Alfred Hospital each nurse is allowed a clear twenty-four hours off duty every week in addition to a fortnight's annual vacation. Some correspondence on the subject has been published in the daily press, some nurses affirming that the hours are too long, others that they are not, and the opinions seem about equally balanced.

Cases of Cerebral Surgery.

At the last meeting of the Medical Society of Victoria ten cases of cerebral surgery were shown. The first was a patient aged thirty, under the care of Mr. G. A. Syme. When first seen in August, 1893, the symptoms were epileptiform, convulsions beginning in the right side of the face, spreading to the right arm and leg, and then becoming general. They were preceded by a sense of constriction in the throat and a numb feeling in the tongue and right side of the face. For some days after the attack the right side of the face and the tongue were paralysed, and the speech thick. Vision, visual fields, and optic discs were normal. There was no vomiting, and no loss of sensation. There was no personal or family history of tubercle, and no history or evidence of syphilis. It was concluded that there was some irritation of the cerebral cortex over the face and tongue centres, probably a tumour, and operation was advised, but not agreed to until Oct. 22nd, 1894, when the patient had become much worse, suffering from aphasia and agraphia, paralysis of the right side of the face and tongue, and paresis of the right hand. The fits had become more frequent and more severe, and he had pain in the left parietal region. The skull was trephined over the face and tongue centre, and a tumour 2.3 by 1.9 inches in size and two ounces and a half in weight removed. It grew from the dura mater and pressed on the lower portion of the ascending frontal convolution and the posterior part of the second and third frontal convolutions. The tumour was encapsuled and microscopically was a small round-celled sarcoma. Speech and motion were gradually recovered, and when shown nearly four months after operation the paresis of the face and tongue was hardly noticeable, the speech was good, he could write perfectly, had no pain, and had had no fits. There was no evidence of recurrence. The second case was under the care of Dr. W. Moore. The patient, aged nine, was suddenly seized with a convulsion, and became unconscious, with right hemiplegia. She had suffered from a discharge from the left ear for several years, which became worse, with earache and pain on the left side of the head ten days previously. The temperature was 102.6° F. A diagnosis of temporo-sphenoidal abscess was made, and the skull trephined in the usual way. The brain was explored in several directions with a grooved director and a trocar and cannula, but no pus was found. After the operation the temperature became subnormal, and the pulse 60. The paralysis and aphasia remained. Five days afterwards the wound was reopened and the brain again explored, when pus to the extent of about two ounces was evacuated from the temporo-sphenoidal lobe. The abscess was drained, and the patient gradually improved, regaining speech and power in the leg, but the arm remained weak, with some contraction of the fingers.

The Etiology of Summer Diarrhoea of Infants.

Dr. R. R. Stawell has been investigating this subject in Melbourne and arrives at pretty much the same conclusions as those reached by inquiries into the causes of this very prevalent complaint in other parts of the world. He has been unable to satisfy himself that any atmospheric condition other than increased temperature has any appreciable or constant influence upon the disease. The increased temperature acts as a causative factor, because at about 60° F. putrefactive processes and toxicogenic germs first become active, and not by causing great depression in the patient, as the charts he had made out showed that the greatest prevalence of the disease was not at the time of the greatest heat; the breast-fed infants are not affected. He thinks there is a small number of delicate children who suffer from diarrhoea in consequence of putrefactive changes in sound food after it has been swallowed.

Two Cases of Didelphic Uteri, with Hematocolpos and Pykopolpos.

In the February number of the *Intercolonial Quarterly Journal of Medicine and Surgery* Dr. F. C. Batchelor of Dunedin records two cases of the above rare abnormalities.

In each case there was a double uterus and a double vagina. Retention of the menstrual fluid occurred in the right vagina in one case and in the left in the other. As a result of distention a rupture occurred through the upper portion of the vagina in both cases, and an escape of the retained menses followed, but not completely. Subsequently septic changes ensued in the pent-up secretions, causing pykopolpos.

Obituary.

SURGEON-GENERAL SAVILLE MARRIOTT PELLY, C.B., F.R.C.S.

SURGEON-GENERAL PELLY, who died on April 3rd at Woodstock House, Lea, Kent, was the last surviving son of the late Judge John Hinde Pelly, of the Indian Civil Service and a brother of the late Major-General Sir Lewis Pelly, K.C.B., K.C.S.I., M.P. He was one of seven sons, six of whom entered one or other of Her Majesty's services, and three attained to the rank of general officers. Born in India, he was sent to England for education, and made his home with a relative, the baronet of the same name. He was then placed at Winchester, where, owing to the marvellous facility he had of getting out of scrapes he received the nickname of "Proof Pelly." As an instance of the good luck which never deserted him, he used to relate how that once, when staying with friends in Gloucestershire, he took compassion on a poor stray dog that had found its way into the grounds. Whilst in the act of fondling it he was startled by the arrival of the whole country side, armed with guns and staves, in search of this very dog, which was mad and had already bitten several persons. On leaving Winchester he began his medical education at the Bristol Royal Infirmary, where he was for some years dressing pupil under Mr. Birchard Smith, then the senior surgeon, and where an uncle on his mother's side was on the hospital staff. He next entered as a student of Guy's Hospital at the time when Bright and Addison were physicians, and Astley Cooper was still alive. It is interesting to note that Dr. J. G. Swayne, whose name is so intimately associated in all our memories with the Bristol Medical School, was a fellow student of Pelly both at Bristol and Guy's. He was a student when Sir Astley Cooper died in 1841, and was one of those who lined the way to the hospital chapel, in the vault of which the body of that distinguished surgeon is deposited. After finishing his professional studies he entered the Indian Medical Service, and was soon ordered to the front. He was present in July and August, 1843, with a field force under Major Blood in the southern parts of Sind, and served with the Sind Irregular Horse during Sir C. Napier's campaign in 1844-45 against the predatory tribes on the borders of Cutchee, and in the surprise and capture of Shahpoor on the night of Jan. 15th, 1845, being favourably mentioned in the despatches by Captain Jacob. He was present with the army of observation at Bhawalpoor under Sir C. Napier in 1846-47, and with the Sind Horse during the pacification of the frontier of Sind in 1847-48 under Major (afterwards General) John Jacob. He served with the 2nd Regiment of Light Cavalry in Rajpootana during the Mutiny campaign in 1857-58, and was present as senior medical officer at the attack on Nimbhaira, the action of Jeerun, and throughout the siege of Neemuch under Captain Simpson, joining afterwards in the pursuit of Tantia Topee with the column under Brigadier Parke. At the conclusion of the war he received the Indian medal and clasp for Central India. For many years he was resident in Sind, and when he was moved on to Poona the *Sindian* of that date contained the following paragraph: "Dr. Pelly will be much missed in the circle he leaves to-day. He is one of the oldest residents among us, having seen service since about the year 1844. He knows the country thoroughly and has watched the progress of its various communities from the first. We still entertain a hope that he may again return to Sind, where he is so well known and so universally popular." As he rose in his profession he became Inspector of Prisons in the Bombay Presidency, and at his suggestion the Government introduced gardening as prison labour, whereby a great saving was effected; for not only was the health of the prisoners greatly benefited by this open-air exercise, but all the vegetables required by the inmates were thus obtained without purchase. When

the Abyssinian expedition was determined upon he was selected for the post of principal medical officer of the Indian Medical Department, and he served throughout the campaign in 1867-68 under Sir Robert (afterwards Lord) Napier. For his services during this expedition he was recommended for the K.C.S.I., but as it was found that this knighthood could only be conferred for services rendered in India he was rewarded by a Companionship of the Bath. Meanwhile he had risen in his profession to be Deputy Inspector-General of Hospitals in the Bombay Presidency, and he retired as Inspector-General in 1870. After his retirement he lived for many years in Dublin, but came to London a few years ago to be near his brother, who was at that time representing Hackney in the Conservative interest. At the quinquenary festival of Winchester College, held two years ago, Surgeon-General Pelly was among the oldest of the Old Wykehamists present, and this visit to the scenes of his boyhood afforded him the keenest sense of pleasure. He was a man of a most warm-hearted and genial disposition, making friends wherever he went, being universally respected for his uprightness and gallantry. Firm in will and strong in action, brave and courteous, punctilious in matters of honour, yet kind, gentle and forgiving, he possessed all the qualities most to be admired in a soldier and a surgeon. He retained to the last a very remarkable intellectual vigour and an activity of body worthy of a man twenty years younger. In his retirement he amused himself chiefly with his lathes, turning out all kinds of articles useful and ornamental, having always had a strong taste for engineering. Among other things he made an electric clock, every wheel of which he forged with his own hands, and he had been at work at an electric stethoscope which was to enable every member of a class to listen to the same heart whilst the physician was demonstrating its defects. He enjoyed perfect health until five weeks before his death, when he was first seized with angina pectoris, associated with some fever, apparently influenza. Dr. Green, of Lee, who attended him, discovered a mitral bruit and gave him relief by medicine and rest; but attacks of cardiac asthma became frequent, and a week before his death Dr. Pye-Smith saw him in consultation. He died suddenly (as had been anticipated) whilst sitting in his chair, on Wednesday, April 3rd, aged seventy-six. He leaves a widow, two sons (the Rev. Stanley Pelly and Captain Saville E. Pelly), and two daughters.

GEORGE HENTY, M.D. ST. AND., M.R.C.S. ENG.,
CAMDEN TOWN.

The death of Dr. Henty removes from north London an old practitioner, aged seventy-seven, who took an active part in all that interests the profession and in much that interests the public. Dr. Henty was born at Chatham and educated at the Grammar School, Rochester. He was afterwards assistant for six years in Princes-street, Hanover-square, to Dr. McDonald. Thereafter he qualified and went into practice at West Malling, and afterwards at Newington, Kent. In the latter place he lived sixteen years, and was medical officer of health. He interested himself in getting a railway station built and other improvements. In 1865 he returned to London and settled in Camden Town, where he had been working until within a few days of his death, which was due to pneumonia; for some months past, however, his health had been much impaired. For seven years he was medical officer to the Aged Pilgrims' Society. He was also medical officer to the Foresters' club. Dr. Henty was an active promoter of the Great Northern and Central Hospital. He was a member of the committee. Though partly responsible for the clause in the constitution under which pay patients are now admitted, he strongly disapproved of the method by which that clause has been put into force. He was also lately hon. sec. of the N. District of the Metropolitan Counties Branch of the British Medical Association, and in this connexion exerted himself against all questionable methods of practice. For the year 1893-94 he was President of the North London Medical and Chirurgical Society. His genial nature and his large experience made his company always acceptable in medical circles.

JAMES JOHNSTON, M.B., M.R.C.P. LOND., M.R.C.S. ENG.

DR. JOHNSTON, who passed quietly away on April 11th in his seventy-second year, had for many years held a prominent place among the medical profession in Birmingham. He

was the son of Mr. Thomas Johnston, a well-known inhabitant of the town, and studied medicine at Queen's College, becoming a member of the Royal College of Surgeons of England in 1844, and Bachelor of Medicine of London University in 1846. Having settled in Birmingham he in course of time came to have one of the largest practices in the town. About 1867 he went to live some miles away, at Wyde Green, a small place close to the ancient borough of Sutton Coldfield, of which town he was for three successive years elected warden. In 1874 he became a Member of the Royal College of Physicians and shortly after this was appointed honorary physician to the Queen's Hospital and to the Hospital for Children. In 1875 he was elected President of the Midland Medical Society, and in 1879 President of the Birmingham Branch of the British Medical Association. About 1897 he left Wyde Green and resided in Birmingham for the remainder of his life. Dr. Johnston lived an honourable, just, and useful life, and was universally esteemed. He was twice married, and four of his sons follow their father's profession.

WILLIAM METCALFE, L.S.A. LOND.

THE little village of Clapham, near Lancaster, has just sustained a heavy loss in the death of its medical man, William Metcalfe, L.S.A. Lond. The deceased had been ailing for nearly two years from obscure abdominal symptoms, which became accentuated some two months ago, and he gradually sank from exhaustion and died on April 8th at the early age of thirty-four. A necropsy showed the cause of death to have been stricture of the small intestine and melanotic sarcoma affecting the stomach and bowels. His terrible sufferings were borne with great fortitude. He was a student of St. George's Hospital, London, and in 1888 he entered into partnership with Mr. Bradley of Benthams, with whom he was connected at the time of his death. He was a successful practitioner and endeared himself to a large *clientèle*, who will long miss his cheery voice and smile.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. Rinaldo Ossola, Lecturer in Forensic Medicine in the University of Roma.—Dr. Wladimir Tomsa, Professor of Physiology in the Bohemian University of Prague.—Dr. Richer, Professor of Therapeutics in the Amiens Medical School.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board in the subjects indicated at the quarterly meeting of the Examiners under the four years' regulations, viz:—

Part I., Chemistry and Physics:—

Bentley, Harry, Owens College, Manchester.
Carter, Joseph, King's College, London.
Cooper, Frank, Mason College, Birmingham.
Evans, John, St. George's Hospital.
Henerey, John Philip Edmund, St. George's Hospital.
Lindsay, Alexander William Crawford, St. Bartholomew's Hospital.
Macmaster, Hugh, Sydney University and Surgeons Hall, Edinburgh.
Oliver, Norman Henry, Guy's Hospital.
Owen, John Griffith, Charing-cross Hospital.
Russell, Francis John, London Hospital.
Simpson, Fred. Algernon, Cambridge University and St. Mary's Hospital.
Sykes, Reginald, Yorkshire College, Leeds.
Whyte, Frederick William, Queen's College, Belfast.
Willson, Arthur Herbert, Oxford University.

Part II., Materia Medica and Pharmacy:—

Agnew, Colville Smith, Charing-Cross Hospital.
Ayre, Frederick John, St. Mary's Hospital.
Carter, Wilfred Becher, St. George's Hospital.
Clarke, Huntley, St. Bartholomew's Hospital.
Collier, Robert Stanley, Yorkshire College, Leeds.
Corfield, Edward Carruthers, St. Bartholomew's Hospital.
Dakin, Thomas Burns, London Hospital.
Davies, Thomas John, Middlesex Hospital.
Day, James John, Middlesex Hospital.
Dearden, Charles Henry, Yorkshire College, Leeds.
Evans, David Edward, London Hospital.
Fanning, William Joseph, St. Thomas's Hospital.
Ferguson, James Herbert, St. George's Hospital.
Herbert, Herbert, London Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Cádiz*: Dr. P. Ramon y Cajal has been appointed Professor of Histology.—*Freiburg*: Dr. Goldmann has been promoted to an Extraordinary Professorship of Surgery, and Dr. E. Jacob to an Extraordinary Professorship of Dermatology.—*Prague (German University)*: Dr. W. Czermak of Innsbrück has been appointed to the chair of Ophthalmology in succession to Dr. Schnabel.—*Vienna*: Dr. Julius Schnitzler has been recognised as *privat-docent* in Surgery.

HER Royal Highness Princess Mary Adelaide, Duchess of Teck, is to be present at the annual meeting of the Factory Girls' Country Holiday Fund on Monday, April 29th. By the kind permission of the Master and Wardens of the Haberdashers' Company the meeting will be held at their Hall in Gresham-street. Alderman Sir David Evans, K.C.M.G., who will preside, will be supported by the Archdeacon of London, the Rev. and Hon. J. G. Adderley, Mrs. Garrett Anderson, M.D., Lady Frances Balfour, Sir Gainsford Bruce, and others.

FOOTBALL CASUALTIES.—On the 12th inst., at Shipley, in a match between the Shipley and District teams, the Bradford wing three quarter back fractured the fibula of his left leg and was conveyed to the Bradford Infirmary.—On the 13th inst., at Northallerton, in a Richmondshire League match between the Northallerton Thistles and Northallerton Central teams, a player dislocated his ankle.—On the same day, at Redruth, during a match between the Plymouth and local teams, one of the visiting half-backs sustained concussion of the brain; and at Burnley, in a League match, two members of the Sunderland team received injuries—namely, the foot of the half-back and captain of the team was caught by an opponent, and the "sudden jerk twisted his leg, almost wrenching his kneecap off," while the other player dislocated his humerus. On the 15th inst., at Armley, in a game between the Burley and Stanningley Clubs, a player received a kick and was removed to the infirmary, but the injury was found to be only slight.

ROYAL METEOROLOGICAL SOCIETY.—At a meeting of this society held at the Surveyors' Institution on the 17th inst. Messrs. F. C. Bayard and W. Marriott communicated a paper on the Frost of January and February, 1895, over the British Isles. The cold period which commenced on Dec. 30th and terminated on March 5th was broken by a week's mild weather from Jan. 14th to 21st, otherwise there would have been continuous frost for sixty-six days. Temperatures below 10° F., and in some cases below zero, were recorded in parts of England and Scotland between Jan. 8th and 13th, while from the 26th to the 31st and from Feb. 5th to 20th temperatures below 10° occurred on every day in some part of the British Isles. The coldest days were Feb. 8th to 10th. The lowest temperatures recorded were -17° at Braemar and -11° at Buxton and Drumlanrig. The mean temperature of the British Isles for January was about 7°, and for February from 11° to 14° below the average, while the mean temperature for the period from Jan. 26th to Feb. 19th was from 14° to 20° below the average. The distribution of atmospheric pressure was almost entirely the reverse of the normal, the barometer being highest in the north and lowest in the south, the result being a continuance of strong northerly and easterly winds. The effect of the cold on the public health was very great, especially on young children and old people. The number of deaths in London due to diseases of the respiratory organs rapidly increased from Feb. 2nd to March 2nd, when the weekly number was 1448, or 945 above the average. Rivers and lakes were frozen, the ice being more than ten inches thick. The frost will long be remembered for its effect on the water-pipes all over the country, in many cases householders being without water for more than nine weeks. As the result of inquiries Messrs. Bayard and Marriott find that mains have frozen which have been laid as low as 3 ft. 6 in. from the surface of the ground to the top of the pipe. It appears, however, that the nature of the soil had far more to do with the depth to which the frost penetrated than the intensity of the frost itself. From a comparison of previous records they are of opinion that the recent frost was more severe than any since 1814.

WIGAN MEDICAL SOCIETY.—An ordinary meeting of this society was held on April 11th, the President, Mr. Wm. Mitchell Roocroft, being in the chair. The President gave his address and read a paper on a Plea for Early and Thorough Excision of the Breast for Cancer. After going fully into the pathological histology of breast cancer he pointed out how necessary it was to remove the breast with all the diseased tissues and glands if recurrence of the disease is to be prevented. A vote of thanks was accorded to the President for his able and valuable address, on the motion of Dr. R. Prosser White, seconded by Mr. E. H. Monks. The remainder of the time of the meeting was occupied in showing cases. Mr. Hugh E. Jones showed: (1) Double Optic Neuritis in a boy eleven years of age; (2) Inclusion Cyst of Eyeball. Mr. Lowe: (1) a case of Traumatic Atrophy of Upper Extremities and Scapular Muscles in a male adult; (2) Erb's Paralysis in a youth aged eighteen years. Mr. Hardman: (1) a case of Scorbatus in a girl aged seven years; (2) a specimen of Ileocolic Intussusception. Dr. R. Prosser White: a case of Purpura. Mr. Berry (hon. sec.): a case of Double Osteotomy performed six months ago.

HUNTERIAN SOCIETY.—An ordinary clinical meeting was held on April 10th, at the London Institution, Mr. Charters J. Symonds, President, being in the chair. Dr. Arnold Chaplin showed a case of Transposition of the Viscera in a healthy girl aged nine. Dr. Galloway showed three cases of Skin Disease: (1) Lichen Planus diffused over the body and limbs of a man aged twenty-eight; (2) the same disease localised about the knees and thighs of a woman; (3) a case of skin disease affecting almost, but not quite, exclusively the limbs of a child aged two years and a quarter, closely resembling lichen planus, but actually caused, Dr. Galloway thought, either by drugs or a micrococcus. Dr. F. J. Smith, Mr. Cotman, and Dr. Chaplin spoke on the cases. Mr. Openshaw showed the following cases: (1) Webbed Fingers (total) in the Left Hand of a little Child, with Partial similar Deformity in the Other Hand; (2) an Enormous Naevus in the Cheek of a Boy aged about twelve, growing since infancy and involving the Palate as well; (3) Double Cephalæmatoma in a Child four weeks old; (4) and (5) two cases of Trephining for Cerebral Abscess, one on either side of the Brain; (6) a case presenting almost identical symptoms to 4 and 5, leading Dr. Hughlings Jackson to diagnose Cerebral Abscess, but the patient gradually got well without any operation. Mr. Cotman showed a case of Intermittent Pulse in a man aged seventy-three; the condition was apparently quite physiological.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Easter Recess.

THE two Houses of Parliament are in recess. The House of Lords adjourned on Tuesday, April 9th, and the House of Commons a day after, and both will resume on Monday, April 22nd.

The Case of Dr. M. J. Calahan.

Mr. William Redmond has given notice that on the day the House resumes he will direct the attention of the Chief Secretary to the Lord Lieutenant of Ireland to the case of this gentleman who after receiving an appointment from the Nenagh Board of Guardians and Dispensary Committee was subject to certain injurious treatment by the Local Government Board.

The Fisheries Bill.

When this Bill comes on for second reading Mr. T. R. Buchanan, many of whose constituents are deeply interested in the matter, will bring forward a motion calling upon the Government to introduce provisions with regard to the regulation of trawling.

Institutions for Idiots.

A Bill has been introduced into the House of Commons to exempt from poor and other local rates all registered institutions for the care, training, and education of idiots and imbeciles. The Bill is backed by Mr. Round, Mr. Ainsworth, Sir Frederick Mappin, Mr. Maclure, Mr. Tomlinson, Mr. Allison, and Sir William Houldsworth, and has been put down for second reading on Monday, May 6th.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ADOLPHUS, J. F. P., M.R.C.S., has been appointed Resident Medical Officer at the Camberwell New Workhouse.

ARKLE, O. J., M.D., M.R.C.P., has been appointed Assistant Physician to the Charing-cross Hospital.

BAMBER, H., M.B., C.M. Glasg., has been appointed Medical Officer for the Tynemouth Sanitary District of the Tynemouth Union.

BOND, E. T., M.D. Lond., M.R.C.S., has been reappointed Medical Officer of Health for the Gloucester Combined Sanitary Districts.

CAPEE, H. N., L.R.C.P. Lond., M.R.C.S., has been appointed Junior Medical Officer to the Brookwood Asylum, Woking, vice Shepherd, resigned.

CHIDLEY, T. J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Clinical Assistant to the Richmond District Lunatic Asylum, Dublin.

DAVIS, W. T., L.R.C.P. Lond., M.R.C.S., has been appointed a District Medical Officer for the Llandilofawr Union.

DUGGAN, MOTHERWELL, M.R.C.S., L.R.C.P., L.M. Edin., has been appointed Medical Officer of Health to the Bowdon Rural Sanitary District.

EVANS, F. W., M.D., C.M. Aberd., M.R.C.S., has been appointed Honorary Assistant Physician to the Monmouthshire and South Wales Infirmary.

EVANS, WM. O., L.R.C.P., L.M., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health and District Medical Officer and Public Vaccinator for the Buckley Sanitary District of the Hawarden Union.

FINCH, H. J., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Assistant House Surgeon to the Royal Surrey County Hospital, Guildford.

FLEMMING, C. E. S., M.R.C.S., has been reappointed Medical Officer for the Eighth Sanitary District of the Bath Union.

GRIFFITHS, P. R., M.B., B.S. Lond., M.R.C.S., has been appointed Honorary Assistant Surgeon to the Monmouthshire and South Wales Infirmary.

GUY, WILLIAM, F.R.C.S., L.R.C.P., L.D.S. Edin., has been appointed Dental Surgeon to the Royal Infirmary, Edinburgh.

LEA, ARNOLD W. W., M.D., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Lecturer on Obstetrics and Gynaecology to the Owens College, Manchester.

MADDLOW, W. H., M.B. Durh., L.R.C.P. Lond., F.R.C.S., has been appointed House Surgeon to the Taunton and Somerset Hospital, vice Bain, resigned.

MILNER, CYRIL W., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Junior House Surgeon to the Nottingham Dispensary.

PATERSON, J., M.B., M.S. Glasg., has been appointed Medical Officer for the Berriew Sanitary District of the Forden Union, vice Morgan.

REDINGTON, J. M., L.R.C.S., L.M., L.R.C.P. Irel., has been appointed *pro temp.* Assistant Medical Officer to the Richmond District Lunatic Asylum, Dublin.

SMYTH, E. J., M.B., B.S., B.Sc. Lond., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Birmingham Workhouse Infirmary.

SQUIRE, E. H., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District of the Lexden and Winstree Union.

TAYLOR, H. S., M.R.C.S., L.R.C.P., has been appointed Junior House Surgeon to the Clayton Hospital, Wakefield, vice Hutley, resigned.

VACHELL, H. R., M.D., C.M. Aberd., M.R.C.S., has been appointed Honorary Assistant Physician to the Monmouthshire and South Wales Infirmary.

VERNON, H. H., M.D., F.R.S. Edin., M.R.C.S. L.M., has been appointed Medical Officer of Health for the Southport Urban Sanitary District.

WATERFIELD, R., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Clinical Assistant to the Richmond District Lunatic Asylum, Dublin.

WILSON, R. M., M.D., B.Ch. Dub., has been appointed Honorary Medical Officer to the Derbyshire Hospital for Sick Children, vice Wright, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM CITY ASYLUM.—Resident qualified Clinical Assistant. Board and apartments provided.

BRADFORD INFIRMARY.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

BRADFORD INFIRMARY AND DISPENSARY.—Junior House Surgeon, unmarried. Salary £50 per annum, with board and residence.

CHARING-CROSS HOSPITAL, London, W.C.—Curator and Pathologist. Salary £100 per annum.

CHelsea.—Temporary Assistant Medical Officer for the Workhouse and Infirmary. Salary at the rate of £120 a year, with furnished apartments, rations, washing, coals, and gas, and an allowance of £2 7s. 6d. for the period in lieu of beer. Applications to the Clerk to the Guardians, 250, King's-road, Chelsea.

CONVALESCENT HOSPITAL AND SEA-BATHING INFIRMARY, Southport.—Resident Medical Officer. Salary to commence at £150 per annum, with board, lodging, and washing.

HOSPITALS FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, W.C.—Surgical Registrar, for one year. Honorarium of £40 at the expiration of that term.—Anaesthetist, for one year. Honorarium of £15 15s. will be voted at the expiration of that term.—Medical Officer as House Physician for six months; unmarried. Salary £20, with board and residence in the hospital.—Resident Medical Officer as House Surgeon for six months; unmarried. Salary £20, with board and residence in the hospital.

LIVERPOOL STANLEY HOSPITAL.—Senior House Surgeon. Salary £20, with board, &c.

MIDDLESEX HOSPITAL, W.—Assistant Surgeon.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Albany Memorial, Queen-square, London, W.C.—Registrar for two years. An annual honorarium of 50 guineas attaches to the office.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS, 32, Soho-square, London, W.—Resident Medical Officer for six months. An honorarium of £10 10s., with board, residence, and washing.

PARISH OF ST. MATTHEW, Bethnal-green.—A male Second Assistant Medical Officer for the Workhouse at Waterloo-road, E., for six months. Salary £40 per annum, with rations, furnished apartments, and washing. Applications to the Clerk, Guardians' Offices, Bishop's-road, E.

PLYMOUTH BOROUGH ASYLUM, Ivy-bridge, Devon.—Locum Tenens, Medical, for four weeks. Terms, £3 3s. per week, with board and lodging.

ROYAL SOUTH HANTS INFIRMARY, Southampton.—Assistant House Surgeon for six months. £10 will be given at the end of that period if found satisfactory. Board and lodging provided.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Resident Medical Officer, for six months. Salary at the rate of £100 per annum, with furnished apartments and board.

ST. LUKE'S HOSPITAL, London, E.C.—Clinical Assistant, for six months. Board and residence provided.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, Albert Embankment, London, S.E.—Lecturer on Physiology.

UNIVERSITY OF GLASGOW.—Two Examiners. The appointment will in each case last till Dec. 31st, 1896, at the rate of £50 annually.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—Medical Officer to the Provident Dispensary attached to the Hospital. Salary £20 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BURD.—On April 8th, at Okehampton, the wife of George V. Burd, Surgeon, of a daughter.

DUKA.—On April 11th, at Jasper House, Wetherby-road, S.W., the wife of Albert Duka, M.A., M.R.C.S., &c., of a son.

GWYTHYR.—On April 11th, at Upper Woburn-place, Tavistock-square, the wife of James Gwyther, M.B., of a daughter.

HENDERSON.—On April 6th, at Via Cavour, Florence, Italy, the wife of Thomas Henderson, M.B., C.M., M.D., of a son.

MARRIAGES.

HEBBLETHWAITE—BARNARD.—On April 18th, at the Parish Church, Owston, Lincolnshire, by the Rev. H. E. Clarke, Vicar, assisted by the Rev. Canon Andrews, Vicar of Saxilby, assisted by the Rev. J. Pettifore, Alfred George Hebblethwaite, M.R.C.S. Eng., L.R.C.P. Lond., of Devonshire-street, Keighley, eldest son of George Hirst Hebblethwaite, Esq., of Westroyd Mirfield, to Annie Blackburn, third daughter of John Barnard, Esq., C.C., of Hemdyke House, Owston Ferry.

LONGTON—PONTIFEX.—On April 15th, at the Consulate, Pau, France, George Harold Longton, M.R.C.S., L.R.C.P., youngest son of Dr. Longton, J.P., The Priory, Southport, to Ella Constance Clark, fourth daughter of Major W. Pontifex, of Chilworth Manor, Guildford.

MORNIHAM—JESSOP.—On April 17th, at the Parish Church, Leeds, by the Rev. Canon Stratten, Vicar of St. Paul's, Leeds, assisted by the Rev. E. Spencer Gough, Rector of Barmingham, the Rev. Arthur Needham Claye, Vicar of Brigg, and the Rev. A. R. Light, Curate of St. Michael's, Headingley, Berkeley George Andrew Moynihan, M.S. Lond., F.R.C.S., of 5, Woodhouse-square and 33, Park-square, Leeds, only son of the late Captain Moynihan, V.C., 8th (King's) Regiment, to Isabella Wellesley, second daughter of Thos. Richard Jessop, F.R.C.S., of Rounday Mount and 32, Park-square, Leeds.

OLIVE—PRICE.—On April 16th, at Christ Church, Leeson-park, Dublin, by the Rev. Canon Neligan, D.D., Eustace John Parke Olive, M.A., M.D. Cantab., F.R.C.S. Eng., of Leamington, to Annie Gordon, eldest daughter of Rev. Wm. Guari Price, Knock, Belfast.

DEATHS.

FORSYTH.—On April 12th, at Smalley, Derby, Thurstan Forsyth, L.M. Dub. (1864), L.R.C.P. Ed., L.S.A. Lond. (1871), aged 55.

HENTY.—On April 11th, at his residence, Camden-road, N., George Henty, M.D., aged 77.

HOLMAN.—On Jan. 25th, on board the *Ganges*, William Holman, Surgeon, eldest son of Commander Robert Holman, R.N.

SKIPTON.—On April 14th, at his residence, Sweet Briars, Liscard, Cheshire, in his 66th year, Deputy-Surgeon-General (Retired) Samuel Stacy Skipton, M.D.

VINRACE.—On April 9th, at Bromford House, Six Ways, Birmingham, Selina Emelin, the beloved wife of John Vinrace, M.D. Interred at the cemetery, Barnes, S.W., April 17th.

WEBB.—On April 10th, at Kingsbridge, Devon, Florence Phoebe, the devoted wife of William Henry Webb, M.D., aged 45.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.). At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Samuel West: Case of Pleuritic Effusion (Serous) of Eighteen Months' Duration; tapped forty times, and side then incised; ultimate complete recovery, with complete expansion of lung and little flattening of side.—Dr. Archibald Garrod: Case of Scleroma Neonatorum ending in Recovery.

TUESDAY.—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-sq., W.).—Dr. Felix Semon: On the Probable Pathological Identity of the Various Forms of Acute Septic Inflammations of the Throat and Neck, hitherto described as Acute Edema of the Larynx, Edematous Laryngitis, Erysipelas of the Pharynx and Larynx, Phlegmon of the Pharynx and Larynx, and Angina Ludovici.

WEDNESDAY.—HUNTERIAN SOCIETY.—8.30 P.M. Mr. F.R. Humphreys: On the Desirability of Forming an Organisation with the view of Correcting the Grievances arising from the Abuse of Hospitals, Dispensaries, and Clubs.

FRIDAY.—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Lucas Benham and Mr. Silcock: A case of Acute Intestinal Obstruction due to Volvulus of the Sigmoid; Abdominal Section; Recovery.—Mr. Golding-Bird: Cases of Early Erosion in Inflammation of the Sacro-iliac Joint.—Mr. Mansell Moullin: Two cases in which Orchotomy was performed for Enlargement of the Prostate.—Mr. Bowly: A case of a Large Intra-thoracic Cystic Gout causing Dyspnoea and treated by Operation.—Mr. Arbuthnot Lane: A case of Extensive Degenerating Nævus of the Bladder.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—SOCIETY OF ARTS.—8 P.M. Mr. James Douglas: Recent American Methods and Appliances employed in the Metallurgy of Copper, Lead, Gold, and Silver.

TUESDAY.—ROYAL INSTITUTION.—3 P.M. Prof. George Forbes: Alternating and Interrupted Electric Currents (I.). GRESHAM COLLEGE.—6 P.M. Dr. Symes Thompson: The Climate of Egypt and Sea Voyages. (First Gresham Lecture.) SOCIETY OF ARTS.—8 P.M. Mr. Wm. Gowland: Art of Casting Bronze in Japan.

WEDNESDAY.—GRESHAM COLLEGE.—6 P.M. Dr. Symes Thompson: The Climate of Egypt and Sea Voyages. (Second Gresham Lecture.) SOCIETY OF ARTS.—8 P.M. Mr. R.E. Crompton: The Use of Electricity for Cooking and Heating.

THURSDAY.—ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The Liquefaction of Gases (I.). GRESHAM COLLEGE.—6 P.M. Dr. Symes Thompson: The Climate of Egypt and Sea Voyages. (Third Gresham Lecture.) SOCIETY OF ARTS.—4.30 P.M. Mr. J.W. Parry: The Coming Railways of India and their Prospects.

FRIDAY.—GRESHAM COLLEGE.—6 P.M. Dr. Symes Thompson: The Climate of Egypt and Sea Voyages. (Fourth Gresham Lecture.) ROYAL INSTITUTION.—9 P.M. Mr. John Hopkinson: The Effects of Electric Currents in Iron on its Magnetisation.

SATURDAY.—ROYAL INSTITUTION.—3 P.M. Mr. Arnold Dolmetsch: English Music and Musical Instruments of the 16th, 17th, and 18th Centuries (with illustrations upon original instruments). (I.)

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

UNDER no circumstances do the Proprietors authorise the insertion of loose advertisement circulars and handbills in THE LANCET. Any such announcements are inserted by the newsagents, whom the Proprietors cannot control. At the same time, the Manager will be glad if readers will send him copies of any circulars, with the name and address of the agent through whom they obtain THE LANCET, and the Manager will then endeavour to mitigate the nuisance.

QUACKERY.

To the Editors of THE LANCET.

SIRS.—The following account of quackery rampant in the West of England may interest some of your readers, although I fear it is by no means unique.

There lives in a neighbouring town a herbalist and "cancer curer," who pays us periodical visits here and swindles the people with an impudence and impunity scarcely credible to anyone unacquainted with the gullibility of the public in all matters medical. One market-day in the present month he stood with his vehicle in the market-place here. By his side was a girl he professed to have cured. She had been a club patient of mine, and endorsed all his statements—I daresay in perfect good faith. He went on to say that this girl had been under my care for many months (mentioning me by name), and under that of another medical man, and had received no benefit whatever, kindly remarking that he did not wish to say anything against us, but that "doctors do not understand these cases." He, on being consulted, at once saw it was a cancer and cured her. He then drew attention to the suppositions "cancer" contained in a bottle hanging at the side of his cart. The above account has been given to me by credible witnesses present in the crowd. Now for the real facts of the case. This young woman was under my care for some time suffering from scrofulous disease at the lower third of the femur, several pieces of bone coming away. She then went into hospital for a considerable time, and on her return continued under my care until the sinus was healed, some thickening of the soft tissues remaining. For this she seems to have consulted the herbalist, who gave her some very irritating ointment, which she was to rub in daily, and which, he said, would bring away a lump, which she was to bring to him. Of course, the ointment produced a slough, which in due time separated, and was transferred to the bottle and dignified by the name of "cancer," and the girl will go to her deathbed firmly believing she has been cured of a cancer which never existed. He then told the people that for this case he had received only thanks, but that for future cases he should charge £10—£5 to be paid down and £5 on completion of the cure.

This is not the only case that has come under my immediate observation. In November last I received a message from another patient, a married man, saying that he was in intense pain and, it was feared, would be dead before I could arrive. I found him with all the symptoms of irritant poisoning, and his mother gave me the following information. Three weeks before this time he had consulted the herbalist, who informed him that he was suffering from the inevitable tapeworm, and gave him a draught and a powder, for which he charged ten shillings, instructing him to wait until "four days before the full of the moon," then fast for twenty-four hours, and finally mix them together and swallow the lot. He did so, and was rewarded by violent pain in the bowels, constantly vomiting, fifteen liquid stools,

ending in a state of collapse, the worm being conspicuous by its absence. The medicine bottle had been destroyed—whether as part of the spell or as a wise precaution in case of unpleasant results I know not. The patient continued under my care for four weeks, and, I believe, was afterwards treated as an out-patient at a hospital. I doubt whether it would be wise to advertise the fellow by taking any public cognisance of him or his doings. I have therefore only sent him a verbal message to the effect that he has very narrowly escaped a charge of manslaughter, and a caution not again to make free with my name. As he carefully avoids using any such title as "M.B." (Medical Botanist), &c., it is possible that he need not trouble himself about the law; but in that case what practical advantage have we from our long and expensive course of study? If a law to meet such cases exists, who is to put it in force? For my own part, of two evils I prefer the lesser, and do not propose to risk the loss of time and money and incur the worry incident to putting the law and its glorious uncertainty in motion.

I am, Sirs, yours faithfully,

March 26th, 1895.

A TWENTY YEARS' SUBSCRIBER.

TREATMENT OF DIPHTHERIA BY SULPHITE OF MAGNESIUM.

To the Editors of THE LANCET.

SIRS,—Since the treatment was brought forward in your columns by Dr. Brownlow Martin some eighteen months ago I have adopted it in all the cases of diphtheria that have come under my care, and have followed, as far as I could, the general indications given for its application—viz., frequent insufflations, tabloids, and a gargle occasionally; and herewith I give a short summary of the results obtained from ten cases of undoubted diphtheria. Of those ten there were two deaths and eight recoveries. The first, a baby fifteen months old, died five hours after it was first seen, and in its case any treatment whatever would have been unavailing. The second, aged thirty-two years, died after six days' illness from pure asthenia, went steadily down, and succumbed from an overdose of diphtheritic poison, notwithstanding a literal deluge of sulphite.

Of the recoveries six ran a course varying from fourteen to twenty-eight days, counting from the appearance to the disappearance of the last trace of membrane, each exhibiting throughout that period the usual and characteristic intermissions and exacerbations so peculiar to diphtheria, and the onset of each recurrence of symptoms coinciding with a re-formation or extension of the membrane, and the intermissions or subsidence of symptoms with successive separations. As an illustration of this, the most usual course, let me give briefly the case of a girl aged six years. I was called to see her on Jan. 30th, 1895, and found the temperature 103° F., with a patch on the right tonsil, &c. I at once gave instructions that the sulphite powder be applied once every hour during the day, and twice during the course of the night; a supply of tabloids was given, and also a mouth wash of the sulphite supplied by way of variation. She was docile and obedient child, and submitted patiently to the treatment in all its details, which I knew were rigorously carried out. By Feb. 2nd all general symptoms had subsided and the temperature was normal, with only a small speck on the right tonsil. Although the tongue was still dirty and coated, we began to hope that her recovery would prove permanent. In this, however, we were disappointed, because by Feb. 3rd a fresh onset occurred irrespectively of the most persistent exhibition of sulphite, and the temperature rose again to 103°, with now a patch on the left tonsil. By Feb. 5th again both tonsils were clear of membrane, and all the symptoms had again subsided. These alternate subsidences and recurrences continued, the diphtheritic membrane invading successively the soft palate, the left side of the uvula, and ultimately the posterior nares; and the last of the membrane was coughed up on Feb. 20th, the tongue began to clear, and convalescence thenceforward was uninterrupted. In the remaining two cases no recurrences or relapses took place, the patch disappearing twenty-four hours after the treatment was begun. As regards sequelæ, a man aged twenty-eight years, one of the six cases, suffered from exceptionally severe paralytic sequelæ, so that at one time his life was very much despaired of. Beginning with paralysis of the soft palate and dysphagia, there followed presbyopia, paralysis and paresis involving the lower limbs, upper limbs, the abdominal and thoracic muscles, and ultimately the sphincters were temporarily implicated too.

I offer no remarks on the results of this treatment. Every case had sulphite powder freely and frequently applied; still my colleague has a record quite as successful with boracic acid and glycerine applications. In my hands I cannot see that the course of the disease has been materially shortened or modified, the majority relapsing under its most persistent administration. That it exerts some influence on the membrane I am prepared to admit; but from former experiences of diphtheria I should like to draw attention to the important and often very misleading feature—viz., that the membrane of diphtheria, quite irrespectively of treatment, seems to be shed or to separate spontaneously after some thirty-six or forty-eight hours from its appearance, re-forming again rapidly and repeatedly—of course, in bad cases. In estimating, therefore, the potency of any treatment this fact must be clearly borne in mind. In conclusion, I regret to have to admit that my confidence and reliance on this sulphite treatment grow less, and if pharyngeal cases can only be overcome or checked after an average three weeks' continuous treatment, what success can we be assured of in dealing with laryngeal cases?

I am, Sirs, yours faithfully,

April 15th, 1895.

JOHN SUTHERLAND, M.B., B.Sc. Edin.

AN APPEAL.

We gladly give publicity to the following appeal:—

"A lady, the daughter of a medical man, has supported herself for the last twenty-five years by teaching; but ill-health has prevented her from continuing to gain a livelihood by this means. She has since started a boarding-house, and is urgently in need of help. Debts to the amount of £150 have been incurred, and her furniture is likely to be taken, and thus her last means of carrying on a home, which is just beginning to maintain her, will be lost. Will any member of the profession assist? Any subscriptions will be received and duly acknowledged by J. Blake Maurice, M.D., F.R.C.S., Lloran House, Marlborough."

"MEDICAL ADVERTISING AT NOTTING HILL AND THE METROPOLITAN PROVIDENT MEDICAL ASSOCIATION."

To the Editors of THE LANCET.

SIRS,—In your issue of the 13th inst. you call attention to a circular referring to the Notting Hill Dispensary and the Metropolitan Provident Medical Association. Will you kindly allow me to state the facts of the case?

The Notting Hill Provident Dispensary—an institution of more than thirty years' standing—has recently been transferred to this association to be carried on as one of its branches. In connexion with the reorganisation of the dispensary a new medical staff has been appointed, and changes made in the hours of attendance, scale of payments &c. The circular to which you refer was drawn up to inform the existing members of the dispensary of these alterations. It was intended only for them, and was not printed with a view of being distributed broadcast, as your note seems to imply. Owing to a misunderstanding, which I much regret, and for which the medical men were in no way responsible, a few copies were given to persons who were not members of the dispensary. I may say that only 500 were printed, and many are still on hand. It is quite contrary to the principles of this association to issue circulars or handbills for general distribution, containing the names of the medical men; and in this case the gentlemen mentioned had no knowledge whatever that the circulars were being given to anyone but members. I enclose a list of our council &c., from which you will see that the association would not be likely to countenance unprofessional advertising by or for the medical men attached to its various branch dispensaries.

I am, Sirs, yours faithfully,

CHAS. H. WARREN,

Secretary, Metropolitan Provident Medical Association.
Lamb's Conduit-street, W.C., April 16th, 1895.

To the Editors of THE LANCET.

SIRS,—Referring to a statement appearing in your issue of the 13th inst. concerning the Notting Hill Branch of the Metropolitan Provident Medical Association, we beg you to insert the following reply from us.

We emphatically disapprove of such a method as you allege has been adopted in advertising this institution, and are much pained and annoyed at the publicity which has been given to our names; we have never authorised any such circular to be "scattered broadcast." We have written to the secretary of the Metropolitan Provident Association for an explanation, and we find your informant has grossly misrepresented the facts. We think before giving such publicity to a false report which casts an ethical slur on two members of the profession you should have exercised a little more care.

It is unnecessary for us to defend the Metropolitan Provident Medical Association. We have asked the secretary to forward you their annual report. We believe it to be a genuine provident institution. Amongst the members of the council are Sir Spencer Wells, Sir Sidney Waterlow, Mr. Timothy Holmes, and many other well-known philanthropists. It receives grants from the Hospital Sunday Fund, the Drapers' Company, the Goldsmiths' Company, the trustees of the London Parochial Charities, &c. It is a philanthropic institution, and we shall take care that so long as our names are associated with the Notting Hill branch the rules and objects of the association shall be adhered to.

We are, Sirs, your obedient servants,

G. MALLACK BLUETT, 11, Addison-terrace, W.
HENRY PILLOW, 1, Pembroke-gardens, W.

. We have also had the pleasure of an interview with Dr. Pillow, who assures us that the circular in question has not, so far as either he or Mr. Bluett is aware, been scattered broadcast or placed either under the door or in the letter-box of houses in the neighbourhood, and that he has caused careful inquiries to be made and can find no evidence whatever of such a practice having been carried out. We have pleasure in publishing the above letters and in accepting the assurance of Dr. Pillow and Mr. Bluett that they emphatically disapprove of such a method as was alleged to have been adopted. At the same time, we wish to express our regret that they have suffered pain and annoyance. There must always be risks of misconstruction when the private addresses as well as the names of practitioners appear on circulars whose destination is probably left in the hands of lay officials. Would it not be feasible in the case of such an institution as the Metropolitan Provident Medical Association to arrange some other means by which the actual members of the association could be made acquainted with the address of the medical officer whose services they wished to secure? It seems a little hard that honourable members of the profession should have to suffer misconstruction of their motives from such a cause.—ED. L.

MEDICAL SCHOOLS AND MEDICAL ADVERTISEMENT.

WE can so much attention is being given to the system of medical advertising and to the evils which it entails it would be unfair to restrict our criticisms to those advertisements which are direct and decidedly vulgar. Advertising must be taken in a larger sense and must be held to include all undue obtrusion of one's name, fame, or faculty before a newspaper public. This may be done in many indirect ways. Over some of these the medical practitioner may have little control. But wherever he has control it is his duty to be firm in its exercise, and to forbid the publication of his name. There are many cases in which medical men allow their names to appear from mere inadvertence, and others with regard to which they are, as a letter which we publish this week shows, never consulted till they see them published. Our attention has been directed to the advertisement of the names of the medical staff of a metropolitan school. We are asked if this is professional. Our answer is that such particulars are out of place in the lay press. The general arrangements of the school, fees, and so on may be advertised in this way, but the names of leading physicians, and surgeons, and accoucheurs are unnecessary and unseemly.

Surgeon-Captain C. H. Hale.—1. Full information can be obtained in Laveran's "Thesis on Paludism" and the Monographs of Marchiafava and Celli, translations of which are among the recent publications of the New Sydenham Society.—2. Baker, Holborn.

"DRUGS CONTRA-INDICATED IN PREGNANCY."

To the Editors of THE LANCET.

SIRS,—Your Paris correspondent in the LANCET of March 9th conveys to us the opinion of M. Huguenin that "at the head of drugs dangerous to the pregnant woman must be placed the sodium salicylate, ergot of rye, salicylic acid, and salol." If in your judgment this view is debatable, I beg to submit as it *propos* the following brief narrative:—

In THE LANCET of Feb. 7th (p. 327) and July 11th (p. 75), 1891, notes are given by Dr. Finzi upon "white infarction" of the placenta as a cause of fetal death, and of the opinions of Dr. W. L. Reid of Glasgow relative to the frequent occurrence of this condition in mothers evidencing a decidedly rheumatic history. Not long after these publications the writer was consulted by a fellow countrywoman as to her prospects of ever having a living child. She gave me to understand that her first parturition terminated (eighteen months before) in the birth of a stillborn and perfectly well-nourished male child, which had apparently been dead for several days, during which period she had felt no fetal movements, though previously actively maintained. From the statements of her husband, an intelligent eye-witness of all that occurred, and those of the nurse, I gathered that there had been disense of the placental structures of very decided character, and that it was the opinion of the expert accoucheur in attendance that this condition had been fatal to the infant. Upon interrogation I learned that the parents of my patient had both died from diseases incidental to the cardiac affections following acute rheumatism, and that she was herself subject to subacute attacks of it. Her urine, examined periodically, showed a constantly high specific gravity (1030 to 1036) and great excess of uric acid. My plan proposed included the continuous exhibition of salicylate of soda, salicylate of quinine, or salol p.r.n., with labour to be artificially induced soon after the termination of the eighth month. Upon the occurrence of pregnancy soon afterwards, the date of which could be accurately known, I communicated my plan of procedure to Dr. W. L. Reid of Glasgow, and was fortunate enough to secure his approval "under all the circumstances." As a result the patient passed on in due course, seldom a week going by without daily doses of the remedies indicated, the urine maintaining a specific gravity of 1020 or lower, with greatly lessened acidity, and the general condition, after the early distress of nausea, "quite as good as could be expected," to use her own terms of description. Labour was induced (by the introduction of a bougie) on the date and day proposed six months before, and was terminated naturally by the birth of a living and perfectly nourished female child, which weighed over seven pounds. The placenta was not markedly abnormal, though there might be a suspicion of degeneration commencing on the maternal surface opposite the insertion of the funis, and at points upon its extreme margin. My patient had a perfectly healthy convalescence, nursed her daughter adequately and with much satisfaction to herself for more than six months, when a recurrence of menses, with concomitant symptoms, led to the adoption of artificial regimen. The infant at eight months weighs about sixteen pounds and has had scarcely an hour's illness.

Your obedient servant,

April 15th, 1895.

AN AMERICAN PHYSICIAN.

"A QUERY."

To the Editors of THE LANCET.

SIRS,—At page 909 of your issue of April 6th, in reply to a query in reference to insurance against accident and sickness for medical men, you state that the Medical Sickness Annuity and Life Assurance Society "covers the sickness risk." This implies that accidents are not provided for. Would you, therefore, kindly amend your reply by stating that this society insures against accident as well as sickness?

I am, Sirs, yours faithfully,

F. DE HAVILLAND HALL.

Chairman, Medical Assurance Society.

Wimpole-street, W., April 15th, 1895.

THE CASE OF MR. C. B. TOWNSHEND.

THE following donations have been received in addition to those already announced and are hereby thankfully acknowledged:—

Mr. W. Domett-Stone (London) ...	£2 2 0	Dr. Felix Semon ...	£2 2 0
Mr. Henry J. Butlin ...	2 0 0	Dr. F.B. Lawson (Brighton) ...	0 5 0
Dr. C. R. Walker (London) ...	1 1 0	Dr. Sharkey ...	2 2 0
Sir B. W. Richardson ...	1 1 0	Dr. T. Carter (Yorks) ...	1 0 0
Dr. Meredith Townsend ...	0 10 0	Æsculapius Masonic Lodge 2410, per Dr. ...	
Mr. Herbert W. Page ...	3 3 0	Thos. Dutton ...	2 2 0
Dr. Andrew Wynter (Beckenham) ...	0 10 0	Dr. Pearson (London) ...	1 1 0
Dr. Walter Edmunds (Lambeth) ...	2 2 0	Dr. T. Whipple (London) ...	1 1 0
		W.M.K. ...	0 5 0
		Mr. Geo. Lawson ...	5 0 0

Further donations are earnestly invited by the Rev. H. Townshend, 41, King Henry's-road, South Hampstead, N.W.

"MEDICAL PRACTICE BY TOUTING.—ADVERTISEMENT BY POSTER IN CAMBERWELL."

To the Editors of THE LANCET.

SIRS,—A friend of mine has just brought to my notice an article in your columns animadverting upon Dr. Gallie and his name appearing upon the bills of our mission slate club. I have already apologised to him for most unwittingly compromising him. May I add through your columns that such an impression as your correspondent notes would never have entered my mind, nor the minds of any of the slate club committee? Dr. Gallie was never consulted about the bill nor knew anything about its publication. The only reason his name appeared as it did was that it might help our men's guild slate club. We never dreamed that it would help him by advertising his name; nor do I think it would. If it is a breach of medical etiquette that the practitioner attending members of a slate club should allow his name thus to appear on a poster, then I repeat the deed was done before Dr. Gallie knew anything of it. I regret extremely that he should have been in any way thought to have committed any such breach of etiquette as your correspondent implies.—I am, Sirs, yours obediently,

April 13th, 1895.

J. TETLEY ROWE, Trinity Missioner.

LANGLEY DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow us through your columns to inform intending subscribers to the Langley Defence Fund that the subscription list is shortly to be closed? Since the first notice was published the following additional subscriptions have been received:—

Dr. Clapton ...	£2 2 0	Mr. Parrott ...	£1 1 0
Dr. Routh ...	2 2 0	Dr. Reid ...	1 1 0
Mr. Jollye ...	2 2 0	Mr. F. W. Smith ...	1 1 0
Dr. Gallie ...	1 1 0	Smaller sums ...	2 0 6
Dr. Wharton Hood ...	1 1 0		

As the amount hitherto subscribed falls far short of the sum that Mr. Langley has had to pay to his solicitors it is hoped that more may still be received. It will be remembered that the action for damages arising out of a midwifery case was dismissed with costs so soon as the evidence of Dr. Cullingworth and Dr. Herman had been heard, but that the plaintiff's pecuniary position was such that the entire costs fell upon the defendant. Either of us will be pleased to receive subscriptions.—We are, Sirs, yours faithfully,

April, 1895.

W. RIMBOLD, 2, Surrey-square, S.E.
LAURISTON SHAW, 10, St. Thomas's-street, S.E.

OPHTHALMIA FOLLOWING INFLUENZA.

To the Editors of THE LANCET.

SIRS,—I have seen so many cases of ophthalmia following an attack of influenza during the recent epidemic that it seems certain there is a causal relation existing. That this should be so is not surprising, as the tendency of the disease is to affect mucous membranes. The conjunctivitis has been in all cases troublesome, lasting from one to two weeks, and requiring usually more than one change of treatment. The amount of muco-purulent discharge has been less than is commonly associated with catarrhal ophthalmia. The inflammation has affected both ocular and palpebral conjunctiva. In one case I have seen it complicated with phlyctenular disease of the margin of the cornea.

I am, Sirs, yours truly,

Rickmansworth, April 9th, 1895.

H. W. WEBBER.

WANTED, A BED-REST.

To the Editors of THE LANCET.

SIRS,—Can any of your readers tell me which is the most useful and economical form of bed-rest?—I am, Sirs, yours truly,

April 15th, 1895.

SUBSCRIBER.

During the week marked copies of the following newspapers have been received:—*Manchester Chronicle, Alloa Circular, New York Herald, Scotsman, Cornish Telegraph, Isle of Man Times, Yorkshire Post, Westmeath Examiner, Chorley Guardian, Ayr Observer, Northern Echo, Sheffield Independent, Devizes Gazette, North Devon Observer, Newcastle Journal, Glasgow Evening News, Whitehall Review, Manchester Guardian, Leicester Post, Brighton Argus, Wigan Examiner, Builder, Sussex Daily News, Birmingham Gazette, West Briton, Bury Guardian, Bath Journal, Brecknock Beacon, Kentish Express, Huddersfield Daily Chronicle, Yorkshire Herald, Architect, Times of India, Boston Independent, Cumberland Advertiser, Pioneer Mail, Brierley Hill Advertiser, Bristol Times, Derbyshire Courier, Bradford Observer, Kensington News, Southend Echo, Southport Visitor, Denbighshire Free Press, The Clerk of the Weather, Star, Johannesburg, Blackpool Herald, Poor-law Officers' Journal, Auckland Times, Norwich Mercury, Colchester Gazette, &c. &c.*

An Inaugural Address

UPON

THE WORK OF THE OBSTETRICAL SOCIETY IN RELATION TO THE EXAMINATION AND REGISTRATION OF MIDWIVES.

Delivered before the Society on March 6th, 1895,

By FRANCIS HENRY CHAMPNEYS, M.A.,
M.D. OXON., F.R.C.P. LOND.,

PRESIDENT OF THE SOCIETY; OBSTETRIC PHYSICIAN TO
ST. BARTHOLOMEW'S HOSPITAL.

[DR. CHAMPNEYS commenced his address by a historical review of the position of English midwives, in which he proved their antiquity and showed that movements in favour of their regulation dated from early in the seventeenth century. He continued:]

PROPOSALS FOR THE REGULATION OF MIDWIVES.

In 1813 the Society of Apothecaries endeavoured to persuade Parliament to pass enactments for the examination and control of midwives, making it penal for any woman to practise without a licence gained after examination and given by the committee of the district in which she lived. There were to be twenty-four districts, including London, each with a properly constituted board.¹ In 1869 Dr. Farr, of the Registrar-General's Department, suggested to the Obstetrical Society the investigation of the causes of infant mortality, which was very great, especially among the newly born.² A committee was appointed and a paper of questions sent to every Fellow: "(1) What proportion of births is attended by medical men and by midwives? (2) Are the midwives instructed?" 1. It was stated, in reply, that among the poor population of villages 30 to 90 per cent. were attended by midwives. The same proportion obtained in the large provincial towns, and especially in large manufacturing towns, while in the small manufacturing towns the proportion was less. 2. In answer to the second question, replies in the negative were received from all parts of the country.³ In 1892 the General Medical Council passed two resolutions. 1. In March Dr. (now Sir Henry) Acland proposed, and Dr. Stokes seconded, the following resolution, which was carried: "That a committee be appointed to consider and report whether the General Medical Council has power to make rules for the special education of women, such as may entitle them to obtain a qualification to be certified by the Council, and that the committee do further report for what purpose such qualifications (if any) should be granted." 2. "What are the most desirable means for educating, examining, and certifying in respect of them, with especial reference to midwifery, the management of medical institutions, dispensing, and nursing?" In proposing the motion Dr. Acland stated that "the Medical Act gave the Council the power of providing for the medical necessities of the people." In seconding the motion Dr. Stokes said: "Midwives were practitioners, to a certain extent, of a branch of surgery and medicine. The interests of that large number of the poor who came under the care of these female practitioners ought to be cared for. The Council should not be an examining body, but it should register the qualifications derived from other licensing bodies."⁴

BILLS FOR THE REGULATION OF MIDWIVES.

The following is a brief summary of the various Bills which have been framed for the examination and registration of midwives:—1. In 1813 the Society of Apothecaries, as has been already stated, tried to get Parliament to legislate on this subject, but without success. 2. The Bill of 1878 was part of the Medical Act originally, and was promoted by the General Medical Council. The portion of it referring to midwives was dropped, as it was feared that it might cause confusion between midwives and medical men if both were included in the same Bill. It was introduced into the House of Lords by the Duke of Richmond. 3. A Bill was framed

in 1882 by the British Medical Association, but was never presented to Parliament. 4. A Bill was prepared in 1890 by the Midwives' Institute, amended by the Obstetrical Society, the British Medical Association, and a Select Committee of the House of Commons, but was talked out on the second reading by Mr. Bradlaugh, because he disapproved of midwives being required to produce a certificate of moral character before registration, while medical men were not required to do so. The Bill was dropped on the understanding that a Select Committee should be formed to consider the whole subject. On Nov. 29th, 1889, the General Medical Council resolved: "That this Council regards the absence of public provision for the education and supervision of midwives as productive of a large amount of grave suffering and fatal disease among the poorer classes, and urges upon the Government the importance of passing into law some measure for the education and registration of midwives." In April, 1891, the Royal College of Physicians of London appointed a committee to report on the Midwives Bill, and this report expresses the conviction that legislative action is desirable in order to secure the due education, examination, and registration of midwives; and it further recommends that a Parliamentary Select Committee should be asked for, before whom the question might be fully investigated with a view to legislation.⁵

SELECT COMMITTEES.

On June 17th, 1891, a Select Committee of the House of Commons, appointed to investigate the question of the registration of midwives, reported as follows:—

Report of the Select Committee of the House of Commons on Midwives' Registration, June 17th, 1891.

"Your committee have sat six times and have taken most valuable and important evidence from medical men and practitioners in various spheres of practice both in favour of and opposed to the registration of midwives, and also from trained and experienced midwives. This evidence has shown that there is at present serious and unnecessary loss of life and health and permanent injury to both mother and child in the treatment of childbirth, and that some legislative provision for improvement and regulation is desirable. They have also had evidence showing that there is a wide field for training in midwifery now unused connected with parish infirmaries and home practice in populous places. Their inquiries had been cut short by the approaching early dissolution of Parliament, and they therefore report the evidence, and recommend a continuation of the inquiry in the next session of Parliament."

Another similar committee on Aug. 8th, 1893, reported thus:—

Report of the Select Committee of the House of Commons on Midwives' Registration, Aug. 8th, 1893.

"Your committee have sat four times, and have taken most valuable and important evidence, which, with that given last year at six sittings, includes that of distinguished medical men and women in various spheres of practice, both in town and country, and also from trained and experienced midwives from various districts. Your committee are of opinion that a large number of maternal and particularly infants' deaths, as well as a serious amount of suffering and permanent injury to women and children, is caused from the inefficiency and want of skill of many of the women practising as midwives without proper training and qualification. They find that amongst the poor and working classes both in the country and in towns the services of properly trained midwives have been eminently successful and of great advantage to the community. As proved by the evidence before your committee, the services of midwives are a necessity, and, consequently, every precaution should be taken to discourage the practice of women who are ignorant and unqualified. Your committee are of opinion that by legislative enactment no woman should be allowed to call herself or to practise as a midwife except under suitable regulations, but that the term 'registered midwife' should be protected and restricted to those who have been properly trained and who alone should be placed on the Midwives' Register, and that the vested interests of untrained midwives should be efficiently protected by inserting in any future Bill a clause to the effect that any woman who produces evidence that she is in practice as a *bona-fide* midwife at the time of the passing of the Act shall, without formal registration, be allowed to continue

her calling under the term 'midwife' alone, but shall not be permitted to assume any other title whatsoever. Your committee therefore recommend that a system of examination and registration of midwives should be established, and that for the purpose of admission and examination of women desiring to act as midwives the General (Medical) Council shall be invited to frame rules for regulating: (1) the admission to the Register either by (a) practice or (b) examination, or by both; (2) the conditions of admission to such examinations; and (3) the conditions of such examinations. These rules and regulations should, in the opinion of your committee, be subject to confirmation by the Privy Council; and in the event of the General Council failing to make such rules as the Privy Council can confirm your committee recommend that the Privy Council should invite some other medical body or forthwith cause the rules and regulations proposed in the foregoing paragraph to be framed for the purposes required, and that such rules shall take effect as if they had been made by the General Council and confirmed by the Privy Council. Your committee also recommend that the duty of carrying out locally the provisions of the Act that will be required should be placed in the hands of the county councils. They also are of opinion that greater facilities for the study of midwifery should be provided in workhouses and lying-in hospitals. In conclusion, your committee desire to refer to the apprehension expressed by certain witnesses belonging to the medical profession, lest their interests might be injuriously affected by an improvement in the status of midwives. The great preponderance, however, of medical and other evidence, having regard to both the authority and number of the witnesses, was to a contrary effect. Your committee, therefore, whilst giving due consideration to the expression of such fears, believe that the suggested injury is not likely to prove serious, and they are of opinion that medical men will not only be relieved of much irksome and ill-paid work, but also that improved knowledge on the part of midwives will induce them to avail themselves more frequently, and at an earlier stage than at present, of skilled medical assistance in time of emergency and danger. On this point your committee had full and substantial evidence."

[Dr. Champneys then quoted from the address, of the President, Sir Richard Quain, at the opening of the fifty-fifth session of the General Medical Council, words showing the Council to be in favour of Government education and registration of midwives, though unable to undertake the duties of detail or local arrangements. A charge of the Recorder to the grand jury at the Old Bailey on Jan. 8th, 1894, was quoted, also in support of the compulsory registration of midwives. Dr. Champneys likewise set forth regulations for midwives in foreign countries. He continued:]

THE HISTORY OF THE OBSTETRICAL SOCIETY.

We now come to deal with the history of our own society in relation to this question. On Nov. 4th, 1870, the Council passed a resolution in favour of the institution of a voluntary examination for midwives.⁶ This resulted from a committee under the presidency of Dr. Hall Davis. At the annual meeting of the society on Jan. 3rd, 1872, the scheme of such an examination, with by-laws, was presented to the society and passed unanimously. It is essentially the same as at present, and the law referring to the granting of the certificates runs thus: "V. That, on satisfying the Board of Examiners as to her qualifications the midwife should receive a diploma certifying that she is a skilled midwife competent to attend natural labours." At the annual meeting, Jan. 6th, 1875, the President (Dr. Tilt) in his address said: "Last year Lord Aberdare and Mr. Stansfeld were in office; they favourably entertained the views repeatedly brought forward by the society, and they were prepared to bring in a Bill for the better education and registration of midwives, when a change of Ministry convinced your Council that the question must be left in abeyance. . . . Ours is the only civilised country that has left unregulated the midwifery of the humbler classes, and it is a disgrace to obstetric medicine that there should be no means of preventing an incompetent and drunken woman from assuming the name and the duties of a midwife." In 1873 the Council referred the matter of branch examinations and registration of midwives to a committee, who reported as follows: "The Obstetrical Society of London, having had repeatedly and urgently brought before its notice the sacrifice of human life and

health occasioned by the practice of ignorant midwives, has already instituted an examining board for testing the knowledge of women desiring to follow the calling of a midwife, and has granted certificates to those who have satisfied its examiners." It then proposed methods for branch examinations and for the registration of midwives.⁹ On June 8th, 1877, the President, Dr. West, informed the society that a deputation had waited upon the Lord President respecting the examination and registration of midwives.¹⁰ At the annual general meeting, Jan. 2nd, 1878, the President (Dr. West) again referred to the subject as follows: "His Grace the Lord President of the Council expressed himself as favourable to the principles which the scheme embodies. It was afterwards laid before the Medical Council, who approved its object. In order to correct various legal and technical imperfections it was submitted to Mr. Roscoe, the legal adviser of the College of Physicians." The President then proceeded to deprecate the postponement of a settlement of this question till that of the admission of women to the profession was settled, and he pointed out that if women were admitted to, and even if men were excluded from, the medical profession, the poor, especially in the country districts, would be just as ill provided as at present. He urged the duty of the society, not as medical men, but as citizens, "to secure some guarantee that the poor shall not continue to be exposed to an ignorance and unskilfulness against which the Government of every other civilised country has protected them."¹¹ In 1879 the President (Dr. Playfair) informed the society at the annual meeting that "the principles of the scheme [for the examination and registration of midwives] not only met with the approval of the Medical Council, but were embodied by His Grace the Duke of Richmond in the Medical Acts Amendment Bill, which, but for the troubles in the East, would, there is every reason to believe, have passed both Houses of the Legislature."

THE CERTIFICATE OF THE OBSTETRICAL SOCIETY.

The following is the form of certificate drawn up by the solicitor to the Society, and hitherto in use. It dates from March, 1887¹²:—

"Obstetrical Society of London.

"We hereby certify that _____ has passed to our satisfaction the examination instituted by the Obstetrical Society of London, and that she is, in our opinion, a skilled midwife, competent to attend natural labour."

(Signatures of President, Chairman, Honorary Secretaries, and Examiners.)

(Undertaking signed by the Midwife)

"I undertake to abide by all the rules and regulations of the Obstetrical Society with regard to the duties and conduct of midwives, and to submit to the jurisdiction of its Council in the decision of all matters relating to my conduct as a midwife. I further agree that in case I shall hereafter be convicted of any criminal offence, or be guilty of any act or conduct which in the opinion of the Council renders me unfit or unworthy to hold its diploma, the same may be forfeited by a resolution of the Council, in which case I will, on receiving notice in writing of such resolution, to be served either personally or by leaving the same at my then present or last known place of abode in the United Kingdom, forthwith give up such diploma to the President, or to one of the Secretaries for the time being of the Society; and I agree that my name may be removed from the Register of Midwives kept by the Society, and I promise thenceforward to desist from the use of any designation or title implying possession of such diploma.

(Signature of Midwife.
Seal of the Society.)"

The Council were expressly advised that no technical meaning attached to the word "diploma," and that it had precisely the same meaning as "certificate." In 1889 the chairman of the Board for the Examination of Midwives reported that the Society had added a declaration or *sponsio* (see above), which each midwife would have to sign, in which she agrees to submit to the jurisdiction of the Council in all matters relating to her conduct as midwife, and to give up her diploma if the Council shall consider her conduct such as to render her unworthy to hold it. This she signs in a book and also on her certificate.¹³

CORRESPONDENCE BETWEEN THE GENERAL MEDICAL COUNCIL AND THE OBSTETRICAL SOCIETY.

On Jan. 4th, 1893 the Council considered the following letter from the Registrar of the General Medical Council:—

"General Medical Council, 299, Oxford-street, London, W.,
"December —, 1892"

(Before December 16th.)

"Sir,—In reference to the giving of certificates or diplomas in midwifery, the General Medical Council, at its recent session, passed the

following resolution, which, in the President's name, I have been directed to communicate to you: 'That the President be requested by the General Medical Council to point out to the institutions and persons who grant such certificates that the certificate should be expressed in such a form as not to lead to the impression that it is a legal qualification to practise midwifery.'

"I am, Sir, yours faithfully,

"W. J. C. MILLER, Registrar."

The following resolution was passed by our Council: "That the Secretary be requested to reply to the President of the General Medical Council, to enclose a copy of the diploma of the Society, and to point out that it is merely an expression of opinion on the part of the Society, and that it does not express any opinion as to the competence of the midwife, except so far as concerns natural labour."¹⁴ At the annual meeting, Feb. 1st, 1893 the Chairman of the Board for the Examination of Midwives, after quoting the proportion of failures in successive periods, and their steady diminution owing to increasing competence of the candidates, defined the scope of the Society's certificate as follows: "When it is remembered that the Society's certificate is merely an expression of opinion by the Society that the holder of it is competent to attend natural labour, and that no legislation has taken place, either for the purpose of preventing uncertified persons from calling themselves midwives or even for registering midwives, it is plain that the work which the Society has voluntarily undertaken and carried on for twenty-one years is highly and increasingly appreciated by the midwives and by the public generally."¹⁵ On April 4th, 1894, the Council considered a letter from the Lancashire and Cheshire Branch of the British Medical Association protesting against the promotion of legislation for the registration of midwives.¹⁶ On July 4th, 1894, the Council considered the following resolution from the General Medical Council of May 22nd: "That, in the opinion of the Council, to issue to any person not legally qualified for registration any certificate of competency or other document so framed as to bear a colourable resemblance in appearance or phraseology to a diploma conveying a right to act as a medical practitioner, is a proceeding which directly contravenes the spirit of the Medical Acts, and is accordingly liable to be visited with the condemnation of the Council. The President is, therefore, requested to repeat a warning, already given to certain institutions, and to urge the registered practitioners connected with institutions granting the certificates to nurse-midwives to carefully reconsider the terms in which they are framed, so as to bring them into harmony with this resolution." To this (which was apparently a circular sent to a large number of certifying institutions without distinction, in which no statement appears that the General Medical Council had anything to find fault with in the certificate of the Society) the following reply was sent: "That the General Medical Council be informed that, with regard to the printed resolution passed May 22nd, a copy of which was sent to the Obstetrical Society, the certificate of the Society was drawn up many years ago with a view to avoid the possibility of its being used as a diploma conveying a right to act as a medical practitioner; that it has been subjected to legal criticism on this point, and has been framed in accordance therewith. The Council of the Obstetrical Society feel sure that the General Medical Council appreciate the care which has thus been exercised in accordance with the views expressed in their resolution."¹⁷ On Monday, Dec. 3rd, 1894, the General Medical Council passed the following resolutions: (a) "That the Council, being of opinion that certain documents issued by various societies or persons as diplomas of education and examination in midwifery are 'colourable imitations' of diplomas conferring a legal right to admission to the Medical Register, and both contravene the spirit of the Medical Acts and are calculated to deceive the public, hereby give notice that from the present date the issue of such 'colourable imitations' by registered practitioners will be regarded as conduct infamous in a professional respect." (b) "That in the opinion of the Council the form of the certificate now before the Council, and purporting to be granted by the Obstetrical Society of London on July 20th, 1894, is such that it may be regarded as a document coming within the purview of the foregoing resolution; and that this opinion be communicated to the President and Council of the Obstetrical Society."¹⁸ This action

was taken at the instigation of the Lancashire and Cheshire Branch of the British Medical Association, whose object is stated above.¹⁹

THE SECTION OF THE MEDICAL ACT.

The section of the Medical Act referred to by the General Medical Council runs as follows:²⁰ "If any registered medical practitioner shall be convicted in England or Ireland of any felony or misdemeanour, or in Scotland of any crime or offence, or shall after due inquiry be judged by the General Medical Council to have been guilty of infamous conduct in any professional respect, the General Medical Council may, if they see fit, direct the registrar to erase the name of any such practitioner from the Register." In a debate in the General Medical Council, May 22nd, 1894,²¹ Mr. Wheelhouse claimed that "an attempt was made to evade the conditions of the Medical Act of 1886, and to institute an entirely new class of practitioners, who were only to be partially educated, and in midwifery only." Dr. MacAlister said the Council had no power to prevent persons practising without a diploma, and it was preposterous that they should be asked to say that any person giving a testimonial to another person was guilty of infamous conduct. Such certificates gave no legal qualification to practise, and it was never intended that they should; they were simple testimonials that in the opinion of certain gentlemen a person was qualified to do a certain thing. He had constantly given testimonials to his pupils that in his opinion they were qualified to act as house surgeons or house physicians, but should be very sorry indeed to be charged with infamous conduct for so certifying to his personal knowledge. These certificates were of the same nature. What they were really asked to do was to say that no woman should help any other woman in her labour unless she had a licence to practise. That mere statement was sufficient to show that the whole agitation was preposterous. There were between 10,000 and 15,000 midwives at this moment, and they could practise, whatever the General Medical Council or the Obstetrical Society might do to prevent them. Was it better or worse that these women should have absolutely no education or that some of them should be educated? To prevent any examination or testing of their somewhat imperfect education was to stop that education altogether. The resolution, as proposed, was itself an illegality, and it would not be sustained in the law courts.

[Dr. Champneys then quoted opinions of the medical press in favour of the registration of midwives, and gave the statistics of the examination of the Obstetrical Society since 1872, which showed a regularly increasing number of candidates, with a total number now on the register (including January, 1895) of 2166.]

THE SCHEDULE ISSUED TO CANDIDATES BY THE SOCIETY.

The following is the schedule issued to candidates by the Society:—

OBSTETRICAL SOCIETY OF LONDON.

Regulations for the Examination of Midwives.

The Obstetrical Society of London grants a diploma, certifying that the bearer is a skilled midwife, competent to attend natural labours, on the following conditions:—

Each candidate must submit to the honorary secretaries of the society—

- (a) Sufficient evidence of good moral character.
- (b) A certificate showing that she is not under twenty-one years of age.
- (c) Proof of having personally attended not less than twenty-five labours under supervision satisfactory to the Board of Examiners.

Each candidate will be required to pass (1) a written and (2) an oral and practical examination in the following subjects:—

- (a) The Elementary Anatomy of the Female Pelvis and Generative Organs.
- (b) The Symptoms, Mechanism, Course, and Management of Natural Labour.
- (c) The Indications of Abnormal Labour, and the emergencies which occur in practice.
- (d) Haemorrhage, its varieties, and the treatment of each.
- (e) Antiseptics in Midwifery, and the way to use them.
- (f) The management of the Puerperal state, including the use of the Thermometer and the use of the Catheter.
- (g) The management (feeding included) of new-born Children.
- (h) The duties of the Midwife with regard to the Patient, and with regard to the seeking of Medical advice.

The written examination is held at the Society's Library on the second Wednesday of the months of January, April, July, and October, at 8 P.M.; the practical and oral examination from one to two weeks later.

The fee for the examination is one guinea; in the event of candidate failing to pass half the fee will be returned.

¹⁶ Council Minutes, p. 686.

¹⁷ Ibid., p. 702.

¹⁸ THE LANCET, Dec. 8th, 1894.

¹⁹ THE LANCET, Dec. 8th, 1894.

²⁰ Medical Act, 1858, 21, 22 Vict., cap. xc., s. 29.

²¹ Brit. Med. Jour., May 26th, 1894.

Successful candidates will be required to sign the declaration quoted above.

OBSTETRICAL SOCIETY OF LONDON.

Examination of Midwives.

This schedule is to be filled up and returned to the honorary secretaries, Obstetrical Society, 20, Hanover-square, W., together with the examination fee (21s.), at least fourteen days before the date of the examination—

Name (Full Christian and Surname to be stated).	{
Age.	
Married, Widow, or Single.	{
Present Address.	{
Permanent Address.	{
(a) Certificate of Good Moral Character.	{
(To be filled in and signed by some responsible person, whose address must be stated, who can vouch for the character of the Candidate.)	
(b) Certificate of Age.	{
(A Certificate of Registration of Birth should be sent in; or, if that cannot be obtained, one must be entered here showing that the Candidate is not under 21 years of age, and signed by some responsible person, whose address must also be stated.)	
(c) Certificate of Attendance on Labours.	{
I certify that the above-named has attended not less than twenty-five labours.	
Signed _____	

(No Labour can be counted among the 25 certified unless the Candidate has repeatedly examined and watched its progress, and has diligently attended the Lying-in for at least ten days.)

THE VALUE OF MIDWIVES.

[After stating that it was not his intention to discuss whether midwives are a good or an evil, Dr. Champneys continued:]

The following propositions appear to be established: 1. Any person is at liberty by the law of the land to render aid to any other in time of sickness, if desired. 2. Any person is at liberty by the law of the land to receive such aid from any other. 3. Unskilled aid leads to lamentable consequences to poor mothers and children. 4. "Midwives are a necessity." It follows that midwives, who are a "necessity," must either be unskilled, with lamentable consequences, or skilled, to render services "eminently successful and of great advantage to the community." It also follows that the supply of skilled midwives can only be maintained by some method securing at least a minimum of experience and skill. As regards the experience of examination of midwives and medical students, my own judgment is that, within much narrower limits, midwives who pass our examination give evidence of theoretical and practical knowledge which would not disgrace students who pass the Conjoint examination; this is also the opinion of all of whom I have asked this question—and they are many. The question is not whether midwives shall exist, but whether they shall be as bad or as good as possible. To put the question briefly, absence of examination and registration of midwives means widespread loss of life and health to mothers and children; for not only are midwives a "necessity," but there is no power to prevent any of the Queen's subjects from acting as a midwife. The opposition which has sprung up aims at the abolition of midwives; but it is quite beyond the power of the agitators to do this, and they know it. What they think they can do is to prevent their examination and registration, and they have aimed at our Society as the principal obstacle in their way. As we have seen, this attack, if successful, would merely result in the destruction of life and health of many poor mothers in England. Is it too late to appeal to those who have joined this agitation with insufficient knowledge to consider the misery entailed by the infection conveyed by such women as would alone remain, and the nameless horrors perpetrated by them?

THE INTERESTS OF THE POOR ARE THE ONLY INTERESTS WORTHY OF CONSIDERATION.

As doctors, we have a right to exist only so long as we are required. Midwives have precisely the same claims. If they are required, they will exist; if they cease to be required, they, like us, will cease to exist. Doctors are made for the sick, and not the sick for doctors. A patient is a person who requires a doctor; a doctor is not, in the same sense, a

person who requires patients. A patient is not, primarily, an organism for excreting so many guineas or shillings per annum as an aphid exudes syrup at the titillation of an ant or a cow secretes milk under the blandishments of a dairy-maid. This is a fact often forgotten. If a poor woman requires a doctor for her confinement she can have one. If she prefers a midwife she can have one—trained, certificated, and comparatively safe; or she can have one untrained, uncertificated, ignorant, septic and fatal.

Besides this, our profession claims, or accepts without protest, the title of "noble" which is so often bestowed on it. To what does it owe its nobility? Surely to the unselfishness which is one of its best traditions. Our profession glories in postponing its private interests to the good of the public. It has abolished profit making by secret remedies, and has come to look upon it as really (and not in the sense of the General Medical Council) "infamous." Why is it more infamous for a medical discoverer to make money out of his secret knowledge than for a man in business, such as a brewer, to do the same? Simply on account of this claim of "nobility." In what other profession can you parallel the enthusiastic propagation of the great class of remedies which began with Jenner's vaccination, and have been so marvellously extended at the present day; or of the wholesale benefits of preventive medicine? It is to be remembered that every such improvement means, in the first instance at least, loss of income to the whole profession. And yet no medical man has ever been known to protest against measures for the preservation of life and health, "though it were to his own hindrance." I confess that the bacillus of cholera seems to me to stand on the same footing as those of septicæmia, and that the profession whose glory it is to endeavour to destroy the one should not regard with levity the chances of the spread of the other. I have said that our profession stands alone in its attitude in this respect. Yet I imagine that other professions, who make no such claim to pre-eminent virtue—as, for example, the legal profession—would stand aghast at a proposition which would be likely to set their fellow countrymen by the ears, even if they saw their own profit in such an event. I think that there is little "nobility" to be seen in the present agitation.

REGISTRATION OF MIDWIVES THE BEST PROTECTION OF THE POOR.

The malpraxis of midwives is an argument often used against them. For the malpraxis of unregistered midwives there is no remedy but the common law. Against the malpraxis of registered midwives the undertaking signed by each of our midwives (quoted above) protects the poor, even where the law could not touch the offender.

REGISTRATION OF MIDWIVES THE BEST PROTECTION OF MEDICAL MEN.

The same undertaking guards doctors against the usurpation of medical functions, such as prescribing, by midwives. Any of our midwives so acting is liable to be struck off the register and deprived of her certificate. These irregularities on the part of midwives are simply the result of absence of proper control. Over uncertificated midwives no control is possible so long as they keep clear of the law. Over our own midwives we have a very considerable hold by means of the undertaking signed by each successful candidate, and quoted above. If offences by midwives holding our certificate were only reported to us we would deal with them.

THE LENGTH OF TRAINING OF MIDWIVES.

Among many arguments against the registration of midwives may be mentioned one—that the present length of their training is insufficient. This is purely a matter of money. The midwives are poor women, and find it difficult to procure the money to pay for their present training and examination. In many cases this is provided, partly or entirely, by their more wealthy friends, and often with the view of acquiring the services of a midwife for a country district. In many foreign countries the expenses are defrayed by the State. Until midwives are subsidised, either by the State or by some other extraneous body, it is useless to expect an increase in the length of their training. The means of subsistence must be provided somehow; if by the midwives themselves the course of training must necessarily be short; if it is desired to lengthen it (an object much to be wished) the money must be provided by extraneous aid. But some training is better than no training at all.

THE INTERESTS OF DOCTORS NOT PREJUDICED BY PROPERLY REGULATED MIDWIVES.

But we must remember that the Select Committee (quoted above), after hearing the evidence for and against the proposition that midwives injure doctors, pronounced emphatically that the reverse was the case, and it is within the knowledge of Fellows that midwives are in some districts actually provided by doctors to help them with cases of natural labour among the poor. And even some of our medical schools make use of them.²² It is hard to imagine that the few shillings, which is all that many of the poor can afford for a confinement, can in any sense repay a medical man for the time expended, or that the bodily handing over of all such cases to trustworthy midwives would be anything but an unmixed relief to the hard-worked doctor of poor districts. I expect the real difficulty is the fear of the loss of a connexion, in the absence of a universal agreement in a district to this effect, loyally kept.

THE MOTIVES OF OUR SOCIETY.

The motives of our Society in instituting and carrying on this examination have been (I state it without any qualification) absolutely unselfish and disinterested. We began the work because there was no other competent body to begin it; we have continued it purely from public spirit. We have sought again and again to be allowed to transfer it to a State-regulated machine. For years our examiners did the work without a farthing of remuneration, generally on a night which was their only relief in the course of the tedious task of examining for the Conjoint Board. Our motives in this respect have been tacitly acknowledged, except by an occasional writer to one of the journals. To any such innuendos the answer is plain—the Society never ceases to beg to be relieved of its responsibilities in this respect and of its emoluments. Such, gentlemen, is our infamy.

THE ACTION OF THE GENERAL MEDICAL COUNCIL.

The action of the General Medical Council is still an enigma to us. It might be conceivable that its opinion was that the abolition of midwives was desirable had it not, in common with all the highest and most competent bodies, repeatedly and strongly stated that the examination and registration of midwives were highly desirable, thus emphatically endorsing the work of our Society. But, as its verdict has over and over again been in favour of such work, it is a little difficult to understand so violent a deviation as its last communication. Perhaps this is the parable of the importunate widow over again; and perhaps it has, in a moment of annoyance, vented its wrath, not against those who have troubled its repose, but against an unconscious and innocent object. That it, like other representative bodies, is afflicted with the restlessness of "Irish members," who are not always Irishmen, is quite possible. That it is not in possession of the facts or history of the question is almost certain. It is, indeed, scarcely to be expected of a body containing at the present time not a single English obstetric physician. We do not yet know of what we are accused. That the Act of Parliament ever contemplated so violent a distortion of plain English as is implied by the application of the word "infamous" to work like ours, undertaken twenty-three years ago, and carried out at the cost of much time, thought, and hard work, in a public-spirited and self-denying manner ever since, is inconceivable. That it should threaten to apply such a word to a body of men such as those who have been mainly responsible for the work carried, I venture to think, its own refutation and condemnation. That those who framed the Medical Act ever contemplated the classification of (alleged) defects in a certificate together with murder, theft, and unnatural offences is unthinkable. I have little doubt that when the General Medical Council realises that it is asked to play the rôle of a puppet of a party of interested practitioners its own sense of dignity and of the purposes for which it was created will come to its aid; indeed, this is plainly foreshadowed in one of the speeches which I have quoted. If the General Medical Council is free to call any person or any act "infamous" when it chooses the position of every medical man is most unenviable. What is to prevent the application of this word to the shape of a collar or the colour of a tie? But it is incredible that the Legislature ever intended to hand over any profession to an arbitrary and irresponsible tyranny such as this would be. Indeed, in a recent case in the Court of Appeal, Feb. 23rd, 1894, the Master of the Rolls adopted a definition prepared

by Lord Justice Lopes as applicable to the case—namely, if a medical man in pursuit of his profession had done something with respect to it "which would be reasonably regarded as infamous by his professional brethren of repute." In the face of the work which our Society has done and of the names of the men who have done it, including practically all the leaders of our branch of the profession in London, it is too absurd to think that our action, or their action, would have the remotest chance of "being regarded as infamous by their professional brethren of repute." Surely, in any movement for the saving of the lives of poor women the General Medical Council ought to stand side by side with those who for twenty-three years have been working for this object in a way which ought to command their respect, rather than to run the risk of appearing for a moment as the partisans of a trades-union. That it should appear for a moment in such a light has been a great and painful shock to us. To have such an epithet as "infamous" applied to us makes us no nearer infamy than before, though I confess that I imagined that work such as ours, carried on merely with the object of helping and protecting the poor, deserved another name. But I believe that neither Sir John Williams, Dr. Watt Black, nor I, who have acted firstly as chairmen of the Midwifery Board and afterwards have been called to the presidential chair, and are therefore, perhaps, the most "infamous" among "infamous" men, feel the least ashamed of our work, conscious as we are of our own integrity and of the great injustice which has been done to us all. As regards the form of our certificate, if the General Medical Council had told us that they thought it open to objections we should have at once done what we are now doing, asked for its criticism with a view to their removal. To have helped us to remove any cause of offence would have earned our gratitude. I cannot but think that when it has mastered the subject and had time to think the General Medical Council will regret what it has done, not only towards men as honourable as any of its members—whose life and work are well known to it—but to a meritorious and public-spirited society.

It is a significant fact that the number of candidates for our last examination has hardly ever been exceeded, not less than 114 women having presented themselves, and that in spite of our having held our certificate in abeyance.

If there is one thing certain in the world it is the ultimate triumph of right. It may be opposed—it may be misunderstood—it may be reviled—it may have to suffer; but "Magna est veritas, et prævalebit."

Since the above was written the following communication has been received from the General Medical Council:—

General Council of Medical Education and Registration of the United Kingdom, 299, Oxford-street, London, W., March, 1st, 1895.

SIR,—In answer to your letter of Jan. 14th, 1895, I have to inform you that the Executive Committee of the General Medical Council has passed thereon the following resolution (whereof you will find a copy on the next page).

I am further directed to inform you that the committee passed, in regard to certain other certificates that had been submitted to the Council, the following resolution (whereof you will also find a copy on the next page).

I am, Sir, yours faithfully,
W. J. C. MILLER, Registrar.

Dr. William Duncan,

Hon. Sec. of the Obstetrical Society of London.

Resolved—"That the Executive Committee are of opinion that the words in the diploma 'a skilled midwife competent to attend natural labour' are open to legal objection, seeing that under the Medical Act (1886) Midwifery is one of the three branches in which a regular practitioner must pass an examination in order to obtain a registrable qualification."

"The above-cited words suggest that the holder has a registrable qualification. This both contravenes the spirit of the Medical Act of 1886 and is calculated to deceive the public."

"Again, the formal character of the document, which is described on its face as a diploma, is fitted to deceive the more ignorant part of the public—that part which most needs protection."

"That the Executive Committee request the President and Council of the Obstetrical Society of London to inform the General Medical Council, within one month, what steps they have taken to bring their certificate within the terms of the resolution of the Council."

Resolved—"That as this Council has been instituted to regulate the education of practitioners in medicine, surgery, and midwifery, as well as to enable the public to distinguish between qualified and unqualified practitioners, the Executive Committee cannot approve of any document professing to qualify persons for any practice in medicine, surgery, or midwifery, issued by any body or institution which is not a medical authority under the Medical Act."

The Executive Committee further declare that medical practitioners, who sign such documents, will be liable to the censure of the Council in accordance with the following resolution passed by the Council on May 22nd, 1894.²³

"In the opinion of the Council, to issue to any person not legally

²² Guy's Hospital Gazette, Feb. 9th, 1895.

²³ Minutes, vol. xxxi., p. 45.

qualified for registration any certificate of competency or other document so framed as to bear colourable resemblance in appearance or phraseology to a diploma conveying a right to act as a medical practitioner is a proceeding which directly contravenes the spirit of the Medical Acts and is accordingly liable to be visited with the condemnation of the Council.

The Council of the Society has already taken steps with the view of removing all causes of offence, now for the first time specified, from its certificate. This it would have done in the first instance had it received the necessary information. In doing so it by no means acknowledges that such causes of offence are well founded.

AN ANALYSIS OF THE CASES OPERATED UPON WITH THE MURPHY BUTTON UP TO DATE.

By JOHN B. MURPHY, A.M., M.D. CHICAGO,
PROFESSOR OF SURGERY AND CLINICAL SURGERY, COLLEGE OF
PHYSICIANS AND SURGEONS, CHICAGO; PROFESSOR OF SURGERY,
POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, &c.

A SUFFICIENT time has now elapsed to warrant a complete report of the cases operated on by means of the button and to justify us in drawing conclusions as to the field of its usefulness. The advantages and disadvantages of the device were at first theoretical; they were later sustained or controverted by the results in experiments and in a small number of cases; finally, we have now a very large number of cases from which to draw conclusions, and a sufficient number, I believe, to enable us to make valuable deductions for our guidance in the future. We will consider the cases in groups, and we will pay particular attention to the fatal cases, and endeavour to determine the cause of the fatality—whether it was a result (a) of the disease itself; (b) of the general condition produced by the disease; (c) of the operation; (d) of failure in obtaining a perfect result at the seat of approximation; (e) of a sequel of the operation; or (f) of intercurrent causes. With this general plan as a guide we will take up the subject as follows.

GASTRO-ENTEROSTOMY FOR MALIGNANT DISEASE BY LATERAL APPROXIMATION.

Of this variety we had 27 cases with 9 deaths. In the first fatal case the patient had suffered from severe hæmorrhage for four weeks preceding the operation, and it was hoped that by performing a gastro-enterostomy a contraction of the stomach would take place, and possibly hæmorrhage. The operation was performed in seven minutes, but the bleeding continued as before and ended fatally four days later. The necropsy showed a perfect approximation. In the second fatal case the patient died of exhaustion forty-eight hours after the operation. A perfect approximation was found. In the third fatal case the patient was very much emaciated and depressed before operation and died twelve hours after. The necropsy showed a perfect approximation. The fourth death occurred from exhaustion in twelve hours. The fifth death was in a case in which the smallest-size button was used, as the operator had no other at the time. The button was so small it was impossible for it to hold a sufficient amount of the tissue to retain the margin of a thick wall, as of the stomach, within its grasp; the wall slipped away from the clasp of the button, and the contents escaped into the peritoneal cavity and caused death. The smallest-size button should never be used in any operation on the stomach. The sixth death occurred from circumscribed peritonitis on the third day. On post-mortem examination the approximation was perfect, and in the stomach was found a large ulcer which was probably the source of the infection. There was also cancer of the pancreas, liver, and other organs, all of which contributed to lessen the resistance of the tissues against infection. In the seventh death the patient died of exhaustion four days after operation. There was perfect approximation, no infection, and the button was still in position. In the eighth fatal case the patient died on the seventh day from general suppurative peritonitis. The necropsy showed perfect approximation and the button still in position; the cause of the peritonitis was not given. The ninth death was from septic peritonitis. The button was not pressed tight enough, and one edge of the stomach had slipped away. It will be noticed that four of the nine deaths were from exhaustion, two from imperfect operation,

and three from peritonitis from infection at the time of operation. Are we justified in operating in these extremely emaciated, cachectic patients with cancer of the pylorus? The patients as a rule survive the operation but a very short period of time, when they succumb to the marasmus of the disease, and not to the effects of obstruction of the pylorus. It is my opinion that patients who are not in a condition to stand a pylorotomy should not be operated on. The relief obtained, even where gastro-enterostomy is successful, is so limited that it does not justify the danger and discomfort produced by the operation, notwithstanding that the operation can be performed with the button in from five to seven minutes. These patients suffer much more from shock in operation than those with non-malignant disease, and the regenerative power of the tissues in a patient with malignant disease is much impaired. Therefore in this class of cases I scruple with the point of a needle the surfaces of the peritoneum of the stomach and intestinal wall where they are brought in contact; this hastens the primary adhesions and increases the rapidity of definitive union. A few interrupted sutures half an inch from the button between the intestine and stomach may be necessary where there is great traction of the coil of intestine approximated, but I have so far not found a case in which I considered it indicated. I prefer the Von Hacker position, though the Wölfler may be used. I believe with Dr. Willy Meyer that the former favours the passage of the button into the intestine. If the cancer involves but a small portion of the stomach in the neighbourhood of the pylorus the most satisfactory operation in its ultimate result is a division of the duodenum two inches below the pylorus, closing the proximal end with a Czerny-Lambert suture and joining the distal end to the posterior wall of the stomach with the button. In non-malignant strictures of the pylorus this is the only operation that should be performed. Where the approximation has been made to the anterior wall of the stomach the button has dropped back into the stomach in four cases; in none of them did it give any unpleasant symptoms, and I believe it would have passed as soon as the stomach contracted to its normal size and the patient was up and about. I have not used the oblong button for this operation and do not consider it necessary, as the results so far prove that the opening made by the circular button is ample, and that the scar does not contract. The oblong button has, however, certain merits. It produces a larger opening; it is more easily inserted than the circular, and passes through the intestine with greater freedom as its diameter is only $\frac{1}{2}$ in. The only two cases in which it has been used are the following:—Case reported by Dr. Joseph D. Bryant of New York: "Diagnosis, fecal fistula of long standing. There had been several previous operations for its closure. Operation, May 9th, 1894. Lateral approximation of ileum to descending colon with oblong button (2½ in. in length); button was easily inserted. Convalescence was uneventful. Button passed on fifteenth day." Case reported by Dr. Willy Meyer of New York: "Male aged twenty-two years. Fistula in right inguinal region. History of appendicitis; abscess opened; fecal fistula followed. Laparotomy, May 31st, 1894. Chronic appendicitis; appendix embedded in dense adhesions, perforated; resection of appendix; loose tampon; appearance of fistula which baffled treatment. Aug. 16th, 1894, ileo-colostomy by Murphy's oblong button. Its two halves could be tied in with great ease and did not require a longer slit in the gut for insertion than the ordinary button. Recovery. Button voided without any difficulty on the tenth day."

CONCLUSIONS.

1. Gastro-enterostomy should never be performed on an extremely cachectic patient.
2. The Von Hacker position is preferable.
3. A supporting suture outside of the button is not necessary except for the relief of tension.
4. In non-malignant stricture of the pylorus the end of the duodenum should be united to posterior wall of the stomach.
5. Pylorotomy by the method described below should always be resorted to where possible.
6. The patient should receive liquid nourishment immediately after the effects of the anæsthetic pass away.

PYLORECTOMY.

Pylorotomy is always the most desirable operation for malignant stricture of the pylorus, as it is the only operation

that offers hope of prolonging the life of the patient for a considerable time. When it is successful the patient regains his usual vigour rapidly and is in good physical condition until the disease recurs. The period of immunity frequently extends over many months and occasionally years. By the use of the button the operation of pylorotomy is relieved of its greatest dangers—viz., shock and leakage at the seat of approximation. The operation is best performed in the following manner:—First, ligate the mesentery on the upper side of the stomach, pylorus, and duodenum as a broad pedicle with from three to four double ligatures and cut between. Second, ligate the mesentery on the under side in the same manner; the pylorus can then be lifted well up into the abdominal incision. Third, pack thoroughly around with gauze and place two clamps on the stomach, one above and the other below the place to be incised. Fourth, a circular incision is then made in the stomach, including the peritoneum and muscularis; this is pushed back half an inch and the mucous membrane cut off; the latter is rapidly closed with a continuous suture; the serosa and muscularis are then closed with a continuous Lembert. Two clamps are placed on the duodenum and it is excised. Fifth, one half of the button is then placed in the end of the duodenum and the other half in the posterior wall of the stomach, one inch from the line of suture, and pressed together. We had four operations of this kind reported, with three recoveries. In all of the latter the button passed on through the duodenum. The first case was that of Dr. A. H. Ferguson, operated on on July 25th, 1893. The patient is still living and in excellent health, having gained sixty pounds in weight. The second case was that of Dr. Willy Meyer's. The patient died several months after the operation. The third case died five days after operation. The patient was in an extremely emaciated condition, and though the operation lasted only forty minutes, he was in a critical state all the time until he died. The fourth case was reported by Dr. M. H. Everett, Lincoln, Nebraska. The patient, a male, aged thirty-five years, first complained of stomach trouble eleven years ago. He had never been free from pain since. Five years ago he commenced to vomit, and during the five years he had not passed a day without vomiting. He came under my charge in November, 1894. His stomach was very much distended and there was a tumour perceptible at the pylorus. An operation was performed on Dec. 18th, 1894. An incision in the median line four inches in length was made; the tumour was drawn out; there were no adhesions; the tumour was as large as a small turkey egg. The mesentery was ligated and divided. The stomach was incised one inch from the growth, and a Czerny-Lembert suture used; the duodenum was divided one inch from the growth; an incision in the posterior wall of the stomach was made and the duodenum joined to it with the button; certainly not five minutes were spent in making the anastomosis; the abdomen was closed without drainage. The temperature next day was 99° F. for a few hours, after which time it remained normal. The button was passed fourteen days after operation. A wonderful change is noticeable in the man. He has not vomited; his appetite is enormous; and at this day, twenty-two days after operation, he has gained twenty pounds. The tumour was found to be a fibroma.

CHOLECYSTODUODENOSTOMY.

The operation of cholecystoduodenostomy by this method and the results are most satisfactory. We have 38 operations reported for cholelithiasis, with 37 recoveries and 1 death. The patient lived for seven days following the operation. There was continuous hæmorrhage from the laceration of the liver from the separated adhesions. A large quantity of blood was found in the peritoneal cavity post mortem; a perfect union existed between the bowel and the gall-bladder, and there was no peritonitis. These results were obtained by twenty-two different operators. In my first article on this subject I recommended the removal of only a sufficient number of gall-stones to allow of the insertion of the button. I early abandoned this method, as I saw that it was possible for calculi to remain in the diverticula of the gall-bladder after the button had passed. That this was well grounded was shown in a case referred to me by Dr. J. H. Hoelscher. Two years after the operation she was again attacked with colic in the region of the gall-bladder. A cholecystostomy was performed, and two large calculi were found in a pocket at the upper end of the cystic duct. The gall-bladder from the fundus down to the calculi, a distance of two inches and a half, had contracted to a tube about the diameter of a lead pencil. The stones were crushed and removed. The

patient made an excellent recovery. This is the only case in which there was a recurrence of the symptoms after the operation, and supports the view advanced by me in my original article that the gall-bladder would contract to a tube, and that the opening between the gall-bladder and the intestine would become so small by the contraction of the gall-bladder that it would not admit fæces into the tract. We have had no case of infection of the liver or gall tracts reported as a result of the operation. Failure of union has not occurred in a single case. This is a most striking contrast in this particular to the results obtained with the suture. The theoretical objection expressed that the button might drop into the gall-bladder and be retained there has not been supported by a single case. The danger of hæmorrhage in patients suffering from cholæmia is very great; and the greatest precaution should be exercised in lacerating adhesions in this class of cases, as the hæmorrhage may continue for days and even weeks. The operation of cholecystenterostomy for malignant disease was very unsatisfactory, as there were eight performed with seven deaths. Two died from shock; one from twisting of the small intestine, producing a volvulus before making the approximation. In one case the gall-bladder was so friable from malignant disease that it tore when the sutures were inserted, and after the button was placed in position and the abdomen closed the friable wall gave way and peritonitis ensued. In all of the others the approximations were found perfect on post-mortem examination. While the mortality from the operation is great, not one of the deaths could have been attributed to the method. Still, they all tend to show that the operation for malignant disease is not a justifiable one; and in many of my recent exploratory operations, when I have found a large carcinoma in the pancreas, duct, or neck of the gall-bladder, I have abandoned the operation, and all of the patients have survived the exploration. Cholecystenterostomy is contraindicated in gangrene of the gall-bladder. These cases should be opened and drained externally, and the peritoneum thoroughly protected by packing. The indications for the operation of cholecystenterostomy are: (1) obstruction to the common duct; (2) obstruction to the cystic duct, where cholecystectomy is impracticable; (3) chronic cholecystitis, with thickening of the wall of the gall-bladder; (4) fistula of the gall-bladder where the patient is emaciated from the loss of bile; and (5) carcinoma of head of the pancreas in its early stage.

INTESTINAL APPROXIMATION.

It is in this field that the button has been of the greatest practical value. The pathological conditions demanding its use in this class of cases greatly endanger the life of the patient. The cases may be well classified as follows:—(1) Resection of the bowel for gangrene: (a) for internal obstruction, and (b) for hernia; (2) resection of bowel for cure of fæcal fistula; (3) resection for malignant growths; (4) resection for perforations of intestine, both traumatic and pathological; and (5) resection of the rectum. Of the resections for gangrene of the bowel from internal obstruction we have 14 cases with 1 death. The patient was a child that had suffered from a four weeks' obstruction; she was so weak and emaciated when operated upon that she never rallied, and died in twenty-four hours. Of the resections for gangrenous hernia there were 12 cases with 2 deaths. The first case died forty-eight hours after an operation for strangulated umbilical hernia which had perforated into the abdomen; general septic peritonitis existed at the time of the operation. The necropsy showed continuation of peritonitis, perfect approximation, and the button in position. The second case was a very interesting one, the patient having had a congenital hydrocele of the testicle with an inguinal hernia in a separate sac. The sac of the hydrocele connected with the sac of the hernia at its neck. The patient after a severe exertion found his hernia down and painful. It was reduced in the usual manner, but the pain and vomiting continued. Six days after the obstruction occurred he was brought to me by Dr. Hanna of Winfield, Iowa, who had seen him only a few hours before and made the diagnosis. I found the hernial sac free and empty, but a Littré involving four-fifths of the circumference of the bowel was strangulated in the small opening of the hydrocele sac. This knuckle had perforated into the sac, and the lining of the sac was gangrenous from the infection. A resection of five inches of intestine was made with an end-to-end approximation, the approximated intestine returned, and the abdomen dressed open. The patient's bowels moved six times within the next eight hours. He did not vomit, but his pulse increased in

OPERATIONS ON THE INTESTINES WITH THE MURPHY BUTTON.

TABLE I.—RESECTION, END-TO-END APPROXIMATION.

No.	Date.	Operator.	Diagnosis.	Operation.	Recovery.	Death.	Remarks.
1	Dec. 8, '92	Walker	Strangulated hernia	Resection of intestine, 4 in.	1	—	First end-to-end approximation by button Oct. 21, 1893. Patient in perfect health.
2	April 3, '93	Andrews, E. W.	Femoral hernia, gangrene	Resection of intestine, 18 in.	1	—	Nov. 21, patient in perfect health.
3	June 5, '93	Murphy	Intestinal strangulation	Resection of intestine, 2 in.	1	—	Time for approximation five minutes and a half.
4	July 10, '93	Murphy	Umbilical hernia, gangrene, peritonitis	Resection of intestine, 5 in.	1	—	Forty-eight hours' continued peritonitis; perfect approximation.
5	Oct. 17, '93	Ruth	Tumour of caecum	Resection of caecum and colon, 2 in.	1	—	Nov. 15, excellent health; obstruction six months; child six years.
6	Nov. 12, '93	Bouffler	Femoral hernia, five days' obstruction	Resection of intestine, 4 in.	1	—	Time four minutes and a half.
7	March 25, '93	Sutton	Closure of artificial anus without resection.	Lateral anastomosis	1	—	Aug. 20, excellent health.
8	Sept. 10, '93	Murphy	Faecal fistula	Lateral anastomosis without resection	1	—	Time six minutes; Oct. 24, well; fistula closed.
9	'93	Rogers	Inguinal hernia, gangrene	Resection of intestine, 10 in.	1	—	Button passed seventh day.
10	Sept. 23, '93	Murphy	Faecal fistula	Lateral anastomosis	1	—	Time seven minutes.
11	July, '93	McCall	Faecal fistula, gangrene	Lateral anastomosis	1	—	—
12	Oct., '93	Marcy	Cancer of rectum	Resection of rectum, 4 in.	1	—	Discharged twentieth day.
13	Nov. 16, '93	Cordier, A. H.	Cicatricial band of ileum	Entero-enterostomy	1	—	—
14	July 8, '93	Bacon	Stricture of rectum	Bacon's operation on rectum	1	—	May 31st, good calibre; neither pain nor discharge; rectum soft and pliable.
15	Jan. 14, '93	Murphy	Annular stricture of rectum	Application of button	1	—	—
16	Sept., '93	Beck, C.	Carcinoma of pylorus	Maydl's operation	1	—	Died subsequently from cancer; post mortem perfect union where button was used; no peritoneal adhesion.
17	Dec. 11, '93	Ferguson	Cancer of caecum	Resection of caecum	1	—	—
18	Feb., '93	Beck, C.	Faecal fistula	Duod-jejunostomy	1	—	Button passed twentieth day.
19	Jan. 14, '94	Ferguson	Faecal fistula	Resection of ileum	1	—	Button passed sixteenth day.
20	Jan. 30, '93	Keen, W. W.	Carcinoma of hepatic flexure of colon	Ileo-colostomy	1	—	Death forty-seven days later; ulcer of ascending colon; perforation.
21	Feb. 3, '94	Price, J.	Sarcoma of sigmoid flexure	Resection, 6 in. of sigmoid	1	—	Button passed ninth day.
22	Feb. 24, '94	Meyer, W.	Carcinoma of pylorus	Pylorotomy	1	—	Button voided twenty-first day.
23	March 3, '94	Meyer, W.	Sarcoma of ileum	Resection, 15 in. of ileum	1	—	—
24	Jan. 2, '94	Dodge, W. T.	Faecal fistula	Resection, 3 in. of ileum	1	—	Button voided eighth day.
25	Feb. 16, '94	Dodge, W. T.	Faecal fistula	Resection, 3 in. of colon	1	—	Button passed eighth day.
26	May, '94	Dodge, W. T.	Ileum adherent to ovarian cyst	Resection of ileum	1	—	Patient died eleven days later from complication; union perfect; button found in rectum.
27	*Jan. 15, '94	Lane, W. A.	Sarcoma of meso-sigmoid	Resection, 12 in. of colon	1	—	Button voided on eighth day.
28	May 9, '94	Bryant, J. D.	Faecal fistula (had five previous operations)	Ileo-colostomy	1	—	Oblong button used for first time; passed on fifteenth day.
29	May 14, '94	Shrady, G. F.	Faecal fistula	Lateral approximation	1	—	—
30	Feb. 12, '94	McBurney, C.	Tumour of caecum	Ileo-colostomy	1	—	Infection occurred; see details in history.
31	April 27, '94	Albee	Carcinoma of colon	Lateral anastomosis	1	—	Growth to be resected.
32	Dec. 12, '93	McBurney & Murphy	Faecal fistula	Lateral approximation	1	—	Button passed on ninth day through fistula.
33	April 1, '94	Davis	Adherent ovarian cyst	Entero-enterostomy	1	—	—
34	Feb. 28, '94	McLaren	Strangulated hernia	Entero-enterostomy	1	—	Six inches of sigmoid removed.
35	Nov. 11, '93	Ricketts	Carcinoma of ileum, obstruction	Resection, end to end	1	—	Time for operation ten minutes; death from shock in ten hours.
36	Jan. 29, '94	Midgilton, W. D.	Carcinoma of rectum	Resection of upper part of rectum	1	—	Resection, 2½ in.; completely cured; button passed on twelfth day.
37	Feb. 27, '94	Ferguson, A. H.	Cancer of caecum	Extirpation of caecum, 14 in. of bowel	1	—	Death four weeks later, diarrhoea; necropsy—perfect approximation; opening large as button.
38	Feb. 27, '94	Stewart, W. W.	Gangrenous hernia	Resection, 10 in. small	1	—	Patient in extreme condition; button passed thirteenth day; rapid convalescence.
39	March, '94	Reed, Chas. A. L.	Carcinoma of caecum	Resection of part of caecum	1	—	Button passed twenty-second day.
40	March, '94	Copeland	—	Resection	1	—	—
41	April 2, '94	Newton	Neoplasm of mesentery	Resection, end to end	1	—	Button passed fourteenth day; patient small child.
42	April 7, '94	Dennis	Strangulated hernia	Resection of ileum	1	—	Button passed twenty-second day; wound suppurated; faecal fistula closed twenty-seventh day.
43	May 11, '94	Outerbridge	Carcinoma of transverse colon	Resection, end to end	1	—	Time for operation one hour forty-five minutes; several inches of transverse colon resected.
44	May 12, '94	Meyer, W.	Intussusception, myxo-sarcoma	Resection of ileum, 3 in.	1	—	Button passed eleventh day; perfect recovery.
45	June 1, '94	Cobb, J. O.	Syphilitic stricture	Anastomosis around stricture	1	—	Died fourteen days after, pneumonia; anastomosis perfect.
46	June 4, '94	Murphy, J. B.	Faecal fistula	Resection, end to end	1	—	25 in. of small intestine removed. Opening made by button in previous operation dilated from 3½ to 5 in.
47	June 13, '94	Shimoneck, F.	Strangulated hernia	Resection, end anastomosis	1	—	Button passed on eighteenth day.
48	June 15, '94	McCallum, J. L.	Strangulation of ileum	Resection, end to end	1	—	12 inches of ileum resected.
49	June 16, '94	Meyer, W.	Intestinal obstruction, sarcoma, intussusception	Resect on ascending colon, 12 in.	1	—	Button passed eleventh day; discharged July 24th; died of marasmus Aug. 14th, 1894; necropsy, multiple sarcoma.
50	June 17, '94	Davis, F. A.	Penetrating wound of abdomen, laceration of intestine	Resection, end to end	1	—	Patient never rallied from shock caused by injury, and died in three hours.
51	June 18, '94	Lillenthal	Carcinoma of transverse colon	Resection, 6 in. transverse colon	1	—	Button used 1½ in. in diameter; passed eighteenth day without pain.
52	June 21, '94	Cochens, F. W.	Strangulated hernia	Resection, end to end	1	—	Resection of 26 in.; button passed 180 hours after operation.

OPERATIONS ON THE INTESTINES WITH THE MURPHY BUTTON—continued.

TABLE I.—RESECTION, END-TO-END APPROXIMATION—continued.

No.	Date.	Operator.	Diagnosis.	Operation.	Recovery. Death.	Remarks.
53	June 23, '94	Meyer, W.	Carcinoma of rectum	Resection of rectum 8 in., Kraske Rehn	1	Death July 22; gangrene of lower end of sigmoid with fecal fistula above line of union; button accomplished purpose admirably.
54	June, '94	Cushing, W. B.	Malignant uterine myoma	Resection, 6 in. descending colon	1	Six inches of descending colon embedded in tumour resected with it.
55	Aug. 31, '94	Beck, C.	Carcinoma of cæcum	Resection of cæcum	1	Ends of intestine sutured; lateral anastomosis with button No. 3.
56	Sept. 9, '94	Jones, W. B.	Malignant stricture of sigmoid	Resection, 3 in. of sigmoid	1	Death five days after operation of peritonitis. No effort at union from infection.
57	Sept. 13, '94	Davis, T. A.	Fæcal fistula	Resection, 4 in. of small intestine	1	Fistula from gangrenous hernia.
58	Sept. 14, '94	Peck, G.	Appendicitis—adhesions	Resection, 4 in. of small intestine	1	Obstruction, after operation for appendicitis, from adhesions.
59	Sept. 13, '94	Parkhill, C.	Fæcal fistula (appendicitis)	Resection of ileum	1	End of ileum cut off from cæcum and attached higher up.
60	July 15, '94	Beaver, D.	Gangrenous hernia—fistula	Resection of 3 in.	1	Button passed on seventeenth day; temperature never reached 100° F.
61	Oct. 16, '94	Carpenter, J. G.	Intestinal obstruction	Resection, late anastomosis around stricture	1	Patient died on eighth day of angina pectoris; bowels moved four times in first twenty-four hours, and continued to move regularly.
62	Oct. 23, '94	Peck, G.	Intestinal obstruction	Resection, 6 in. of sigmoid	1	The contraction was produced by adhesions and a fecal fistula following an operation for pyosalpinx two years previously.
63	† Sept. 27, '94	Swain, P.	Intestinal obstruction	Resection, 5 in. of ileum	1	Obstruction existed a long time; proximate end 12 in.; distal contracted; button voided tenth day.
64	Oct. 25, '94	Mullins, C. D.	Intestinal obstruction, four months' standing	Anastomosis of ileum and colon	1	Child in extreme condition when operated on, having had four weeks of intestinal obstruction; death in twenty-four hours.
65	July 5, '94	Day, Donald D.	Intestinal stricture	Resection, 10 in.	1	Button voided in two months, producing no unpleasant symptoms; bowels moved regularly from time of operation.
66	Aug. 7, '94	Williams, R. R.	Double rupture of intestine, traumatic	Resection (double)	1	Both buttons voided eighteen days; patient died from extensive laceration of bladder.
67	July 11, '94	Abbe, R.	Ileo-colic anastomosis	Resection of caput coli	1	Patient died from obstruction by hardened feces in button, notwithstanding ileostomy.
68	June 9, '94	Summers, J. E.	Intestinal obstruction (five days) by malignant growth of sigmoid	Anastomosis around tumour	1	Patient in extreme condition; resection not deemed advisable; anastomosis made in ten minutes; death from shock in twenty-five hours.
69	June 13, '94	Summers, J.	Tuberculosis of tube involving sigmoid	Removal of tube, resection of 5 in. of sigmoid	1	Tuberculosis involved 4 in. of sigmoid; perfect recovery.
70	June, '94	Hartmann	Ileo-cæcal inflammatory adhesions	Resection of cæcum	1	Resection of adherent ileum, cæcum, and colon.
71	June 1, '94	Abbe, R.	Cancer of descending colon.	Resection of growth and loop of intestines	1	A special large size button 1½ in. in diameter used; fitted intestine snugly; sloughing of bowel over button due, I fear, to tension and pressure of metal on account of large size and weight; button from former anastomosis in some cases found resting in loop close to growth; caused no inconvenience (April 27th, 1894); death from peritonitis.
72	Nov. 24, '94	Murphy, J. B.	Gangrenous femoral hernia, four days	Resection, 8 in. of ileum	1	A sac full of feces; bowel ruptured; resection to s. and tissue; drained; four bowel movements in six hours; perfect recovery.
73	July 19, '94	Bell, J.	Intestinal obstruction; perforation; adhesions	Resection, 4 in. of small intestine	1	Bowel ulcerated; perforation sutured; abdomen closed; recovery; tumour not removed.
74	Sept. 11, '94	Bell, J.	Intestinal obstruction; tumour involving bowel	Resection, 3 in. of sigmoid with tumour (cancer)	1	First button found free in splenic flexure above the obstruction, caused no trouble; sigmoid and tumour resected; time two hours; elastic tube used to prevent escape of feces; operation difficult; death four days later; ends of bowels both gangrenous in whole circumference; perforation had taken place just beyond the border of the button; fatal peritonitis.
75	Oct. 12, '94	Bell, J.	Femoral hernia; gangrene	Resection, 11 in. of ileum	1	Sac contained effusive bloody serum; second resection necessary; abdomen closed and radical cure made; perfect recovery; primary union; button voided tenth day.
76	Nov. 1, '94	Murphy, J.	Ileus	Resection, 4 in. of small intestine	1	The intestine was bound down by a band of fibrous tissue; resection; button passed twenty-first day; recovery.
77	Oct. 15, '94	Ullmann	Cancer of cæcum	Resection, 26 in.	1	Patient made an excellent recovery and was exhibited before Medical Society six weeks after operation.
78	Dec. 18, '94	Everett, M. H.	Tumour of pylorus	Resection, 4 in. of stomach, 2½ in. duodenum	1	Button passed thirteen days after operation; uneventful recovery.
79	Dec. 30, '94	Murphy, J. B.	Strangulated inguinal hernia; six days	Resection, 5 in. of small intestine	1	Bowel gangrenous, perforated; congenital hydrocele sac full of pus; large quantity of serum in peritoneal cavity; bowels moved six times in first twenty-four hours; pulse increased continuously in frequency; delirium; no vomiting; death from sepsæmia in thirty hours.
80	Nov. 7, '93	Griffith, J. D.	Rupture of intestine, septic peritonitis	Resection, 5 in.	1	Gas and feces passed off freely through the bowel; death in twelve hours from sepsis and shock.
81	Dec. 18, '93	Griffith, J. D.	Stenosis, ileo-cæcal	Ileo-colostomy	1	Button passed twenty-first day.
82	Mar. 20, '94	Griffith, J. D.	Gunshot wound of large intestine	Resection	1	Death sixty hours after operation from obstruction by adhesions of intestines in a sharp angle at seat of operation, producing obstruction.
83	July 7, '94	Wiggins, F. W.	Double perforation, traumatic	Double anastomosis	1	Line of union in both places barely visible; pressure, atrophy almost complete at seat of adhesions, where adherent bowels protected line of union.
84	Aug. 16, '94	Meyer, W.	Fæcal fistula	Ileo-colostomy	1	Along button used in this case, which passed on tenth day without pain or difficulty.
85	Sept. 30, '94	Wittwer, H. E.	Carcinoma of pylorus	Pylorectomy	1	Time consumed in operation forty minutes; death from exhaustion fifth day. Necropsy—peritoneum dry; no peritonitis; firm union of end of duodenum to posterior wall of stomach; button still in position; stomach very much contracted and full of cherry pits, lime beans, and grape seeds, many of them had passed through button.
86	Oct. 24, '94	Plettner, A.	Carcinoma of cæcum	Resection of cæcum	1	Button passed on fourteenth day without being noticed by patient; discharged on twenty-first day.
87	Oct., '94	Reeve, J. C.	Fæcal fistula (hernia)	Lateral approximation	1	Button voided on fifteenth day; uneventful convalescence; rapid improvement in condition.
88	Sept. 20, '94	Bacon, M. W. & Cory, A. L.	Pyosalpinx tubes adherent	Resection of transverse colon, 8 in.	1	Button voided on eighth day; uneventful recovery.
89	July 1, '94	Davis, T. A.	Fæcal fistula from hernia	Resection, 4 in.	1	Button voided on twentieth day; uneventful recovery.
90	Nov. 9, '94	Lee, E. H.	Gunshot wound of abdomen	Resection, double	1	Two large perforations of large mesenteric arteries, very profuse hæmorrhage; twelve perforations of bowel; two resections of about 12 in.; time of operation forty-seven minutes; patient exsanguinated. Necropsy—no peritonitis; perfect approximations; death thirty-six hours after operation from shock and hæmorrhage.
91	Jan. 18, '95	Fenger, C.	Obstruction of ileum after appendicitis	Anastomosis around obstruction	1	Adhesions so extensive could not be liberated, and lateral approximation considered best.

OPERATIONS ON THE INTESTINES WITH THE MURPHY BUTTON—continued.

TABLE II.—CHOLECYSTENTEROSTOMIES IN NON-MALIGNANT CASES.

No.	Date.	Operator.	Diagnosis.	Operation.	Recovery. Death.	Remarks.
1	June 11, '92	Murphy, J. B.	Cholelithiasis	Cholecystodu- denostomy	1	—
2	Oct. 19, '92	Murphy, J. B.	Cholelithiasis	"	1	—
3	Nov. 23, '92	Murphy, J. B.	Cholelithiasis	"	1	—
4	Dec. 18, '92	Murphy, J. B.	Cholelithiasis	"	1	—
5	Jan. 31, '93	Lee	Cholelithiasis	"	1	—
6	Feb. 20, '93	Murphy, J. B.	Cholelithiasis	"	1	—
7	April 6, '93	Mayo	Obstruction of com- mon duct	"	1	Patient seventy-one years old.
8	April 28, '93	Foster, W. D.	Gall-bladder fistula, obstruction of common duct	"	1	Fistula closed without operation.
9	May 6, '93	Murphy, J. B.	Cholelithiasis, occlu- sion of common duct	"	1	—
10	May 22, '93	Murphy, J. B.	Cholecystitis, im- paction	"	1	—
11	June 1, '93	Fabrique	Hepatic colic, im- paction	"	1	—
12	June 1, '93	Rogers	Closure of biliary fistula after cholecystotomy	"	1	Tenth day removed button through fistula.
13	July 18, '93	Hartmann	Cholelithiasis	"	1	—
14	Aug. 3, '93	Ferguson	Dropsy of gall- bladder	"	1	—
15	Sept. 20, '93	Lane, W. A.	Cholelithiasis	"	1	—
16	Oct. 20, '93	Luken	Cholelithiasis, ob- struction of common duct	"	1	—
17	Oct. 26, '93	Hartmann	Cholelithiasis, ob- struction of cystic duct	"	1	—
18	Nov. 7, '93	Murphy, J. B.	Cholelithiasis	"	1	—
19	Jan. 6, '94	Dunn	Cholelithiasis, ob- struction of common duct	"	1	—
20	Feb. 13, '94	Murphy, J. B.	Cholelithiasis	"	1	Button passed eighteenth day with twenty-six stones. Two 3-in. stones removed.
21	Feb. 24, '94	Abbe	Obstruction of common duct	"	1	—
22	Feb., '94	Barrows	Biliary fistulas	"	1	—
23	Oct. 16, '93	Ferguson, A. H.	Gall-stones	"	1	Excellent recovery.
24	Feb. 6, '94	Moffat, H.	Cholelithiasis after cholecystotomy	"	1	Previous cholecystotomy Nov., '93 14 calculi removed; symptoms returned and cholecystenterostomy.
25	Feb. 22, '94	Ferguson, A. H.	Gall-stones	"	1	Excellent recovery.
26	March, '94	Bradley	Obstruction of common duct	"	1	Post mortem, profuse hemorrhage from liver where it had been torn during operation in freeing adhesions. Approximation perfect. Time of operation forty minutes. Death from exhaustion on seventh day.
27	March 23, '94	Ferguson, A. H.	Gall-stones	"	1	Excellent recovery.
28	April 17, '94	Mynter	Cholelithiasis, en- larged gall-bladder	"	1	Rapid recovery. Button passed twenty-second day—126 gall-stones.
29	May, '94	Bradley	Cholelithiasis, dila- tation of gall- bladder	"	1	150 calculi. Button passed forty days after operation.
30	May 16, '94	Parkhill, C.	Gall-stones	"	1	Button passed twenty-second day. Convalescence uneventful.
31	July 26, '94	Burdick, G. G.	Cholelithiasis	"	1	Button passed fourteenth day. Large calculus allowed to remain in choledochus.
32	Aug. 17, '94	Middleton, W. D.	Cholelithiasis, ob- struction of chole- dochus	"	1	Gall-bladder found contracted to size of Hickory nut; stone such that size removed; obstruction due to fibroid degeneration along entire length of duct. Smallest size button used; rapid convalescence.
33	Sept. 8, '94	Murphy, J. B.	Cholelithiasis, ob- struction of cystic duct	"	1	Time of operation twenty minutes. Difficulty in pressing calculus from duct back into bladder; 60 calculi removed.
34	Sept. 15, '94	Murphy, J. B.	Cholelithiasis, ob- struction of cystic duct	"	1	Gall-stones as large as filberts impacted in cystic duct removed through gall-bladder, which was full of mucus; no bile; patient never had jaundice or colic. Time of removing calculus and making anastomosis six minutes; time of entire operation sixteen minutes.
35	Sept. 15, '94	Werder, X. O.	Cholelithiasis	Cholecystjejuno- stomy, closure of fistula	1	Button passed twenty-seventh day.
36	Nov., '94	Murphy, J. B.	Cholelithiasis, cholecystitis	Cholecystjejuno- stomy	1	A pure cholesteroline calculus 2 in. in diameter removed. Button passed eighteenth day, after vomiting. Largest size button used.
37	—	{ Johnson, G. B. Long, J. W. }	Cholelithiasis, occlusion of common duct	Cholecystduo- denostomy	1	Gall-bladder firmly adhered to colon; Paquelin cautery used for hemor- rhage; gall-stones removed; button passed nineteenth day with two stones. Uninterrupted recovery.
38	Nov. 11, '94	Morris, E. V. D.	Cholelithiasis, en- larged gall-bladder	Cholecyststero- stomy	1	3 ounces of bile in gall-bladder; time thirty minutes; discharged from hospital in sixteen days; button voided in eleven days.
39	Jan. 14, '95	Lindsey, C.	Cholelithiasis, cholecystotomy, fistula	Cholecyststero- stomy	1	Fistula continued discharging after cholecystotomy, Aug. 4th. Operation with button thirty minutes; uneventful convalescence.

OPERATIONS ON THE INTESTINES WITH THE MURPHY BUTTON—continued.

TABLE III.—CHOLECYSTENTEROSTOMIES IN MALIGNANT CASES.

No.	Date.	Operator.	Diagnosis.	Operation.	Recovery. Death.	Remarks.
1	March, '93	Weir	Cancer of pancreas, liver, omentum, and gall-ducts	Cholecystenterostomy	1	Exhaustion; perfect approximation.
2	May, '93	Murphy, J. B.	Cancer of duodenum, pancreas, gall-ducts, and liver	Cholecystojejunostomy	1	Four days; ileus from volvulus; loop of jejunum twisted upon itself.
3	Feb. 2, '94	King, E. W.	Carcinoma of pancreas	Cholecystoduodenostomy	1	No peritonitis; cholémie hæmorrhage from all mucous surfaces of the body; death on fourth day.
4	March, '94	Mynter	Stenosis of common duct	Cholecystoduodenostomy	1	No peritonitis; perfect adhesions; multiple carcinoma of pancreas and liver; death from prostration.
5	Sept. 24, '94	Hartley, F.	Malignant obstruction of common duct	Cholecystocolostomy	1	Button passed.
6	Jan., '93.	Dawbarn, R. H. M.	Cholelithiasis	Cholecystoduodenostomy	1	It was found on introducing the suture that a carcinoma of the gall-bladder as well as gall stones existed. When the sutures were introduced they tore through the cancerous wall as if it were wet paper; the smallest sized button was finally placed and the intestine approximated; death from septic peritonitis; necropsy showed the friable gall-bladder gave way from the clasp of the button. As far as I can learn this was the first time the button was used in New York. Dr. Dawbarn comments: "This case should not count against the method for the reasons mentioned; I have repeatedly demonstrated upon the cadaver that the operation is simplicity itself."
7	Feb. 27, '93	Griffith, J. D.	Cholelithiasis, cholæmia	Cholecystenterostomy	1	Patient had large hæmorrhagic spots all over body at time of operation; necropsy showed large extravasations throughout entire intestine track; no peritonitis; death from exhaustion.
8	March 13, '93	Griffith, J. D.	Cholelithiasis, impaction of stone in duct	Cholecystenterostomy	1	Operation greatly prolonged on account of adhesions; connexion to jejunum.

TABLE IV.—GANGRENE OF THE GALL-BLADDER.

1	March 15, '94	Long, J.	Gangrene of gall-bladder	Resection of gangrenous portion; cholecystenterostomy	1	Gall-bladder extensively gangrenous; contained 195 calculi; death in twenty-four hours; temperature reached 106°; sepsis.
---	---------------	----------	--------------------------	---	---	---

TABLE V.—GASTRO-ENTEROSTOMY.

1	Sept., '92	Murphy, J. B.	—	—	1	—
2	May, '93	Wiener	—	—	1	Four days; continued hæmorrhage from cannula; perfect union.
3	Aug. 9, '92	Murphy, J. B.	—	—	1	Seven minutes.
4	June 7, '94	Logan	—	—	1	—
5	Dec. 29, '92	Barbat	—	—	1	Necropsy, forty-six days; perfect union; no contraction.
6	July 25, '92	Ferguson	—	Pylorotomy & gastro-duodenostomy	1	Time eighty minutes; Sept. 3 patient in good health.
7	March, '93	Schede	—	Gastro-enterostomy	1	Exhaustion; perfect approximation.
8	March, '93	Schede	—	Gastro-enterostomy	1	—
9	Feb. 2, '94	Ferrier, M.	—	Gastro-enterostomy	1	Exhaustion, eighteen hours; perfect union.
10	July 21, '93	Middleton, W. D.	Stricture of pylorus	Gastro-enterostomy	1	Uneventful recovery; patient, up to date, has gained 42 pounds.
11	Dec., '93	Reed, Chas. A. L.	Carcinoma of pylorus	Gastro-enterostomy	1	Button passed nineteenth day; patient died four months later.
12	April 19, '94	Bressler	Obstruction of pylorus	Gastro-enterostomy	1	Death four weeks later; exhaustion; button found at splenic flexure of colon; retained by band of adhesion; no obstruction.
13	April 20, '94	Mynter, H.	Carcinoma of pylorus	Gastro-enterostomy	1	Vomiting ceased; patient left hospital in three weeks.
14	May 5, '94	Quenu	Epithelioma of stomach	Gastro-jejunostomy	1	Time of operation one hour fifty-five minutes; uneventful recovery; up in eighteen days; great increase in weight.
15	May, '94	Mynter, H.	Carcinoma of pylorus	Gastro-enterostomy	1	Smallest size button used, which could not possibly grasp tissue, and was never intended for that purpose; the wall of stomach slipped out of its embrace and allowed contents to escape; death ensued from exhaustion in twelve hours; a running suture is not necessary if proper sized button is used.
16	—, '94	Mynter, H.	Carcinoma of pylorus	Gastro-enterostomy	—	—
17	July, '94	Middleton, W. D.	Carcinoma of pylorus	Gastro-enterostomy	1	Exhaustion; largest button used; patient very weak and emaciated previously to operation from constant vomiting; death on third day; post mortem was revealed circumscribed peritonitis about site of operation; approximation perfect; stomach eroded by a great ulcer 3 inches in diameter; pancreas and other organs involved.
18	July 6, '94	Meyer, W.	Malignant stricture of pylorus	Gastro-enterostomy	1	Rapid recovery.
19	July 4, '94	Mayo, W. J.	Carcinoma of pylorus	Gastro-enterostomy	1	Death fourteen days after; broncho-pneumonia; necropsy; perfect union; button liberated; opening twice as large as button.
20	July 23, '94	Meyer, W.	Carcinoma of pylorus	Gastro-enterostomy	1	Patient still in hospital, doing well.
21	Sept. 13, '94	Lyman, C. B.	Carcinoma of pylorus	Gastro-enterostomy	1	Necropsy; very large carcinoma involving large portion of stomach and duodenum; no peritonitis; perfect approximation; button in position; death from exhaustion on fourth day.
22	Sept. 30, '94	Bryant, E. A.	Carcinoma of pylorus	Gastro-enterostomy	1	Button No. 3 (1 inch in diameter) used, which was voided on sixteenth day; no pain, fever, or vomiting after operation.
23	Sept. 26, '94	Jaboulay	Carcinoma of pylorus	Gastro-enterostomy	1	Button No. 3 used, which passed on fourteenth day; patient made an excellent recovery.
24	Aug. 23, '94	Case, C. E.	Carcinoma of pylorus	Gastro-jejunostomy	1	Necropsy; perfect union at seat of approximation; button still in position; death on seventh day from general suppurative peritonitis.
25	Oct. 12, '93	Griffith, J. D.	Carcinoma of pylorus and duodenum	Gastro-jejunostomy	1	Died two weeks later of exhaustion; patient seventy-two years, and very much emaciated.
26	Nov. 10, '93	Griffith, J. D.	Carcinoma of duodenum and liver	Gastro-jejunostomy	1	Button not pressed tight enough; one edge loose; death from septic peritonitis.
27	—, '94	Monod	Carcinoma of pylorus	Gastro-enterostomy	1	Button voided on twelfth day; Doyen's procedure approximating intestine to posterior wall of stomach through perforation in transverse mesocolon.
28	Oct., '93	Buecking	Carcinoma of pylorus	Gastro-enterostomy	1	Time for operation sixteen minutes; patient died some time after of exhaustion; necropsy showed a perfect union.

! Dr. Murphy's table omits the diagnosis of these nine cases and the operation in the first five.

frequency, and he died thirty hours after the operation with all of the symptoms of auto-intoxication from the decomposing proteids that had been retained in the alimentary canal. There was no peritonitis. This case shows how important it is to act upon the symptoms of obstruction following an apparently complete reduction of a hernia. Of resections for fecal fistula with end-to-end approximation I have had nine cases reported, all of which recovered. Here the results show that the operation of resection with end-to-end approximation promises much more for the patient than the lateral approximation both for the immediate relief of the fistula and the permanent cure, and I now perform it in all cases in preference to the lateral. We have a total of 41 resections for non-malignant diseases, with 2 deaths. If to these be added the seven cases by Dr. Joseph Price, the details of which I have not received, with six recoveries, we have a total of 48 cases with 3 deaths. The first death was due to continued peritonitis and the second to auto-intoxication. In Dr. Price's case the death occurred from shock twelve hours after operation. The operation was the removal of an enormous universally adherent fibroid, also the excision of several inches of the bowel and a portion of one ureter. These results, obtained in the hands of many operators, certainly indicate that the question of operation in gangrenous hernia, internal obstruction, and fecal fistula is definitely settled—i.e., that resection with end-to-end approximation gives all that can be expected in the way of results.

Resection of the intestine for malignant disease with end-to-end approximation does not give us as good results as for non-malignant, as is the case with all operations for malignant disease. Still, when we review and analyse them, they are a great improvement over those obtained by other methods, and on the whole very satisfactory. There were 30 operations with 7 deaths. These include 8 resections of the cæcum with one death. The causes of death in the malignant cases were as follows. In one case infection from without during operation; a perfect approximation was found at the necropsy. One case from shock ten hours after operation. One case from peritonitis. The specimen showed that there was no evidence of effort at union at the seat of approximation, and that the peritonitis was present from the time of operation. In one case which died from peritonitis a special large-size button (one inch and a half in diameter) was used; it fitted the intestine too tightly and produced a sloughing over the surface of the button with perforation. It is important that the button should fit easily in the intestine. One case had fatal peritonitis. The gangrene of both ends of the bowel was attributed to the length of time that the ends were compressed during the operation, and this conclusion is certainly supported by the fact that both ends were gangrenous and that the perforation occurred not at the seat of the pressure atrophy, but beyond the margin of the button. The intestinal clamps which I use on the intestine to prevent the escape of feces and gas cannot produce this condition, as they do not compress the parallel artery of the bowel in the triangle made up by the division of the peritoneal surfaces of the mesentery and the wall of the bowel. This artery is the most important one for the nutrition of the bowel. In one case death occurred shortly after operation, but the cause was not reported. Finally, one case died from exhaustion. Resection for perforations of intestine, traumatic and pathological, with end-to-end approximation. The mortality from perforations, both from gunshot wounds and for perforating ulcers, has always been very great, not that the danger exists in the operation, but in the dangers of the pathological conditions themselves. Luche, in his collection of 322 cases, found that where the operation was performed within twelve hours after the perforation the mortality was 58.2 per cent.; later than twelve hours, 79.5 per cent. In bullet wounds of the abdomen the collapsed condition of the patient, the profuse hæmorrhage, and the shock upon the nervous system all contribute very greatly to the mortality. We can estimate with great accuracy the position of the wound in the bowel by calculating the course of the bullet from the point of entrance to the position in which it is lodged. The bullet commonly passes either (1) from before backwards, in which case we have one or two perforations, or (2) transversely, then we have many perforations in close proximity—i.e., we may have as many as ten or twelve perforations within twenty inches of intestine. The operation should be a resection of the entire perforated coil, an end-to-end approximation, with drainage of the cavity. Where the perforations are a greater distance apart double resections may be made and two

buttons inserted as in a case reported by Dr. R. R. Williams of Manning, Iowa. The operations for pathological perforation of the intestinal tract are, as a rule, postponed too long. The profession has not yet extricated itself from the erroneous belief that the symptoms of collapse occur immediately after the perforation takes place. I would enunciate the following rule, and it should be impressed on the mind of every practitioner. The manifestations of perforation into the peritoneal cavity depend upon the character and quantity of material admitted into the cavity and the pathological changes produced thereby in the peritoneum. By this I mean that the symptoms are not the result of the perforation *per se*, but the result of the pathological changes produced by the result of the perforation.

LATERAL APPROXIMATION.

In cases of fecal fistula resection should be performed in preference to lateral apposition; the same is true in cases of malignant disease. In cases of extensive adhesions it may be impracticable to resect, and lateral approximation must be performed. Of lateral approximations 12 were reported: 5 for malignant disease, with 2 deaths, and 7 for simple obstruction; all recovered.

RESECTION OF THE RECTUM.

This operation has been simplified in its most trying mechanical part—i.e., the drawing down and approximating the upper to the lower segment, suturing it there, and still retaining the sphincter intact. We have reported 3 resections with recoveries, and 2 lateral approximations; that is approximations around the strictures with a pressure atrophy of the stricture, a method in which the button is used, devised and described by Dr. Bacon.¹ The operation of resection with removal of the sacrum (Kraske) and end-to-end approximation with the button was first done by Dr. Henry O. Marcy of Boston.² The method of procedure for resection of the rectum is as follows:—1. In order to do the operation without removing the coccyx or sacrum (Kraske), it is necessary to be able to reach the upper margin of the carcinoma with the index finger. 2. The sphincter should be dilated until it is completely paralysed; the cancer should be drawn down with forceps, and the rectum packed with gauze above. 3. A puckering string should be inserted in and out through the wall of the rectum half an inch below the carcinoma and left perfectly loose. 4. A circular incision is now made through the entire wall of the rectum, a quarter of an inch above the suture, and between it and the carcinoma. 5. The carcinoma and rectum are then liberated from the surrounding connective tissue, and drawn down as a cylinder into the lower segment of the rectum, and the separation continued until well above the carcinoma. 6. Half an inch above the carcinoma another puckering string is inserted, and a circular incision is made a quarter of an inch below this, cutting out the carcinoma. The gauze packing is then removed. The male portion of the button in which is threaded extremely heavy braided silk, double-drawn through the cylinder, is placed above, and the upper puckering string tied around the cylinder of the button and cut short. The stem is held with a small forceps. 7. Slide the female portion of the button over the string and press it up until it barely catches the end of the male cylinder, just sufficient to hold. 8. Make a small parallel incision in the lower segment of the rectum over the coccyx and half an inch below the first puckering string inserted. Through this pass a strand of iodoform gauze for drainage outside of the button. (This may be removed on the third or fourth day, if necessary.) 9. Draw the button well down and tie the first puckering string around the conjoined cylinders; cut the suture short and press the button together by making traction on the cord and pressing up from below. 10. Have the bowels loose before the operation and keep them loose after the operation until the button loosens itself or can be liberated by slight traction about the tenth day. The traction cords may be left in until the button is removed.

CONCLUSIONS.

1. The cicatrix produced with the button does not contract.
2. Size No. 1, $\frac{1}{2}$ in., or No. 2, $\frac{3}{4}$ in., should be used for cholecystenterostomy. I prefer No. 2.
3. End to end, side to side, and end to side of the small intestines should be made with button No. 3, $\frac{3}{4}$ in. in diameter.

¹ The New York Medical Record, Dec. 10th, 1892.

² Medical Record, June 26th, 1894.

4. End to end and side to side of large intestine should be made with button No. 4. 1 in. in diameter.

5. A special large size, 1½ in. in diameter, with a long male cylinder, may be used in some cases of resection of the rectum with advantage, but it should not be used unless it fits loosely.

6. In intestinal obstruction resection with end to end union gives better results than lateral approximation, and should always be performed when practicable. The same operation should always be done in gangrenous hernia. In faecal fistula the bowel should be resected and united end to end.

7. The patients should receive liquid nourishment as soon as the effect of the anæsthetic passes off. The bowels should be made to move as soon as possible after the operation and frequent evacuations kept up.

8. If the button does not pass in three or four weeks, the rectum should be examined, as it may rest just inside the sphincter.

9. There has been one case reported of occlusion of the button by faecal impaction in the cylinder. This can be easily avoided by a mild cathartic immediately after operation.

10. When returning the intestines to the abdomen, they should be placed in parallel lines, especially at the seat of approximation, to prevent sharp curves and obstruction. This occurred once with the button; many are reported following suture.

11. There is no danger from obstruction from the button, as not a single case has been reported. This proves that the deductions made by Choput of Paris from experiments on the cadaver are erroneous.

12. There is no danger of extension of the pressure atrophy beyond the line of pressure.

13. Primary adhesion may be hastened in malignant cases by abrading the peritoneum with a needle. It is unnecessary in non-malignant cases.

14. A supporting suture is never necessary to secure union, and should only be used to relieve tension when the viscera approximated are forced out of position.

15. The mucous membrane should be pushed down in the cup of the button before closing it; if redundant it should be trimmed off with the scissors. It should never be allowed to protrude between the edges of the button when the button is closed.

16. While the button is easily inserted, the pathological condition requiring the operation may demand the greatest surgical skill to secure a favourable result.

17. The following points regarding the construction of the button should be noted before using it. (a) The spring catches should hold firmly in all positions and should be made of a metal that will not be corroded by acids. (b) The elastic pressure cup should be on the male half of the button—never on the female. (c) The edges of the pressure surfaces should be very smooth—hemispherical in shape. (d) The spring under the pressure cup should not be too strong. (e) There have been defective buttons on the market. The following firms are at present manufacturing perfect buttons: J. J. Ryan and Co., Chicago; Truax, Greene and Co., Chicago; Geo. Tiemann and Co., New York; W. F. Ford and Co., New York; Down Brothers, London, England; Sharp, Smith and Co., Chicago; Franz, Kratzmuller and Co., Chicago and Berlin.

18. If the button appears at the opening of the fistula after lateral approximation, do not try to force it through the opening—it is unsurgical; open the abdomen and (a) press the button back to the anastomotic opening and through the latter on down the intestine, and it will pass; or (b) make a longitudinal incision in the bowel and take it out.

THE LINCOLN COUNTY HOSPITAL.—From the 125th annual report of this hospital we learn that the number of patients admitted during the past year was 982, the largest ever admitted since the erection of the institution, and an increase of 142 as compared with those admitted the previous year. Including those remaining as in-patients at the beginning of the year, the total number treated was 1068; of these, 481 were cured, 91 relieved, 319 made out-patients, 32 died, 65 were discharged unrelieved, and 80 remained in hospital at the close of the year. The average length of residence in the hospital of each patient was five weeks, and the weekly cost of maintenance £1 2s. 2½d., as compared with £1 3s. 7d. the preceding year. The total number of out-patients was 4093.

MALIGNANT DISEASE OF THE COLON SIMULATING MOVABLE KIDNEY.

By HENRY MORRIS, M.A., M.B., F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL.

CASE 1. *Malignant disease of the ascending colon mistaken for movable kidney and causing a large perinephric abscess.*—On Oct. 20th, 1889, I was asked to see a married woman aged about forty-three years, who was suffering from a large swelling in the right lumbar region which had been treated as a movable kidney for some months previously. She had recently partly recovered from a severe attack of right-sided pleurisy, and had gone to Worthing for change of air; but a few days after her arrival at the seaside she became very ill with fever, rigors, and a rapidly developing swelling of great size in the right side of the abdomen. She was seen by Mr. Augustus H. Collet, who sent her home in an invalid carriage and communicated with me to take charge of the case. When I saw the patient she was in great distress with much fever, shivering, and considerable œdema of the right loin. The whole right side of the abdomen was distended and dull, and in front there could be readily felt a hard movable mass not unlike the kidney, but situated rather lower than the normal position of that organ. I was told that this somewhat reniform mass had been known to exist for several months, that it had been very movable, and had been regarded by a distinguished obstetric physician and by a general physician as a movable kidney. The large general swelling, with pain, sense of fulness, and œdema in the loin, had only made itself evident a few days. I regarded the case as one of perinephric abscess, and advised that it should be immediately opened, but suggested a physician seeing her before the operation, and Dr. Wilks was accordingly called into consultation. Dr. Wilks agreed that an incision should be made through the loin. This was done on the following day. A very large quantity of pus was evacuated, and two enormous pieces of sloughed cellular tissue were withdrawn. These, when spread out, were large enough to cover a full-sized joint dish. The movable mass was felt to be riding upon the front of this abscess, and sank back into the loin after the evacuation of the pus and when the patient was turned upon her back. The abscess soon healed; the patient immediately improved and became convalescent, but there was no appreciable change in the size of the movable mass. On Dec. 26th there was evidence of renewed inflammation in the loin; a fresh abscess formed and burst on the night of Dec. 29th, through the centre of the scar of the incision. The second abscess soon healed, but still the mass remained, and, after another consultation with Dr. Wilks on Jan. 25th, 1890, it was decided to examine this by laparotomy. On Jan. 28th Mr. Norton gave the anæsthetic, and with the assistance of Mr. Andrew Clark and Mr. Leopold Hudson I made an incision in the right semilunar line to explore the tumour. It proved to be a broad, annular, malignant growth in the wall of the ascending colon and cæcum, and though still movable at its anterior surface it was very tightly bound down by adhesions posteriorly, so that for this reason, as well as on account of the extent of the infiltration of the bowel, excision was not deemed advisable. There was no occasion to perform colotomy as there was no intestinal obstruction. On Feb. 5th all the sutures were removed, and the patient was convalescent from the exploratory operation. The subsequent symptoms were pain, occasional constipation, flatulence, and general weakness, and towards the end emaciation, but no intestinal obstruction throughout the illness. She died on August 13th, 1890, somewhat rapidly, and with symptoms suggestive of ulceration and perforation of the bowel.

CASE 2. *Cancer of descending colon simulating movable kidney in front of perinephric abscess.*—A gentleman forty-seven years of age was sent to me by Mr. Court of Staveley on Feb. 1st, 1887, with the following history. During the preceding six months the patient had suffered on and off with a pain in the left ilio-costal space. About four months ago he had an attack of colic, the pain being in front of the abdomen. He had always been temperate. He had lost about two stones in weight during the six months and had become weaker. For some time a hard smooth mass had been felt, on deep pressure, immediately below the ribs, associated with some tenderness on firm pressure on the loin. He had not been equal to

following his employment since Jan. 17th. On Jan. 21st he had a rigor. At the time I saw him there was much pain over the left kidney, extending back into the loin and down towards the groin in front. His temperature was 100° F. and the pulse 94; the respiration was normal. He was thin and haggard-looking; he walked with a limp, and with his trunk bent somewhat forwards and to the left side. There was a well-defined, somewhat movable, hard swelling felt through the front wall of the abdomen in the position of the left kidney. The left loin felt full and hard and was slightly bulged backwards. It was dull on percussion, and the skin, though not actually cedematous, had a look suggesting that it was so. His urine had a specific gravity of 1030; it contained no sugar or albumen, but he had some increased frequency of micturition, getting up at night to urinate. He was very thirsty. Mr. Court wrote: "The lump, whatever it is, I feel persuaded is at the bottom of his trouble. His symptoms rather point to the kidney, but the swelling is hardly in the normal position of that organ. Is there an abscess with irritation transferred down the psoas muscle? or is there a malignant growth? This latter would account for all his symptoms, but I cannot make up my mind what the exact nature of the growth or swelling really is." To me it appeared that Mr. Court's opinion was as near as one could go, and I wrote down in my case-book: "A perinephric abscess in left loin, with tumour in neighbourhood of left kidney." On Feb. 5th the patient came up for an exploratory operation, but by this time the symptoms had somewhat changed. His temperature since I saw him on the 1st had been 103° at night and 101° in the morning. There was more fulness and hardness in the loin. The skin of the loin looked red, and was decidedly cedematous and the loin was very tender. On Feb. 6th, in Mr. Court's presence, I made an incision into the loin, and evacuated a quantity of very offensive pus from a large riddled space behind the kidney, which extended upwards to the diaphragm and downwards to the pelvis. During the convalescence the discharge assumed a fecal character. The patient returned to Derbyshire on Feb. 22nd with a sinus, which showed marked signs of closing. He did not live long afterwards, however, but died on May 12th, 1887, greatly emaciated. Fæces and pus were again discharged through the fistula, and Mr. Court informs me that at the post-mortem examination he found the descending colon involved in an ulcerated cancerous mass, the left kidney largely destroyed by the same disease, and there were numerous small secondary deposits in the omentum. Both the kidney and colon communicated with the old abscess sac, which was full of fecal matter.

These two cases show the disposition of malignant disease of the colon to cause widespread suppuration in the cellular tissue of the loin and to present a tumour in the lumbar region, which, especially if it excites any renal irritation, is not unlikely to be regarded as of renal origin, and when movable to simulate movable kidney. I might refer to another case, which I saw with Mr. T. W. Nunn and Mr. Balding of Royston, in which I opened a large perinephric abscess, due, there is every reason to believe, to malignant disease of the sigmoid flexure.

Cavendish-square, W.

THE EYESIGHT OF SCHOOLBOYS IN 1894.

By A. ST. CLAIR BUXTON, F.R.C.S. EDIN.,
SURGEON TO THE WESTERN OPHTHALMIC HOSPITAL.

FOR some years past I have from time to time called attention to the unsatisfactory condition of eyesight prevalent among children educated in Board schools. Many a time I have pleaded their cause, though, I fear, with but indifferent success. There are still countless numbers of little ones whose eyes are quite unfit for the close work they have to do, and who are compelled to get through their daily routine as best they may. There is still the same ignorance among their elders, who mistake faulty vision for dulness or worse; and there appears to be still the same degree of apathy on the part of the authorities, whose duty it should be to see that those under their charge and control are in every respect fitted and properly equipped for the task they have to accomplish. The House of Commons has had the matter brought to its notice more than once, but as far as I know the only result

has been a promise that an investigation should be made in some selected schools. What the upshot of this inquiry was, how it was conducted and by whom, or whether it ever took place, is more than I can tell. Feeling strongly on the subject, and finding no evidence of any improvement in the methods of the Education Department being likely to occur, I have devoted no small portion of my leisure during the year 1894 to an independent inquiry. This has been made among boys of the upper and middle classes in grammar schools, in private educational establishments, and in the course of ordinary practice. And here I would tender my thanks to those masters who have so kindly made my work as easy as the circumstances permitted.

On the whole a fairly large number of boys have been subjectively tested for visual acuity and for manifest astigmatism, with what results the following table will show. It may be taken for granted, without much fear of contradiction, that, whatever be the proportion of imperfect vision existing in the higher classes of society, the proportion is still greater, and probably much greater, in the lower grades. Unhealthy surroundings, badly lighted and badly ventilated rooms, overcrowding, want of proper exercise, insufficient food, &c. conduce largely to this. The facts are bad enough even with well-fed and well-cared-for boys, as my table will show. What must they be in the case of those others whose lot and surroundings are in every way less favourable?

Normal. A	Subnormal.				
	B	C	D	E	F
§ and §	§ and §	§ and less than §	§ and §	§ and less than §	§ and § or less
Good	Good with 1; fair with 1	Good with 1; bad with 1	Fair with each	Bad	Very bad
Per cent. 63.54	Per cent. 7.22	Per cent. 4.33	Per cent. 7.58	Per cent. 5.05	Per cent. 12.27

It must be remembered that hypermetropia greatly exceeds myopia in frequency of occurrence, and that the subjects of the former kind of refractive error are often not aware that their eyes are in any way at fault until they are troubled by the accommodation beginning to be "fagged out." This happens, for the most part, in young adult life at an age exceeding that of the schoolboys now under consideration; consequently it is highly probable that a good percentage of those boys whose acuity of vision for distant types is shown as normal in my table are really hypermetropes. It would not be an exaggeration to say that at least 10 or 15 per cent. of the so-called normal boys, Class A, will find difficulty in using their eyes for close work before they are twenty years old; so that, roughly speaking, one may say that very little, if anything, more than half the number of boys examined are really normal as regards vision. This statement is further borne out by the following fact. Of all the boys tested (with Snellen's distant types and the astigmatism fan) nearly 15 per cent. were found to be astigmatic with one eye only, and over 17 per cent. with both eyes, many of the boys who showed evidence of this error (either in one eye or in both) being those who had been able to read the six-metre type at the full distance with each eye, and who consequently figure as "Normal," Class A, in my table.

The difference of opinion which seems to prevail between various observers as to whether bad sight is increasing in England or whether it is not might surely, with some advantage to the public, be removed, and the whole matter cleared up by some such plan as I have adopted in the present instance, but on a much larger scale, repeated at stated intervals—say, of three years. Perhaps some of my younger confrères with sufficient enthusiasm and with more leisure than I can command may think it worth while to carry out this suggestion. If it should be established beyond dispute not only that the average eyesight of our growing boys and girls is decidedly mediocre, but also that the trouble is on the increase (as I am sure it is), then perhaps something may be done towards remedying the evil. My actual figures from which the table was drawn are: number of boys tested, 2493—i.e., in Class A, 1584; Class B, 180; Class C, 108; Class D, 189; Class E, 126; and Class F, 306. The number of boys astigmatic in one eye was 360, and in both eyes 441. Upper Wimpole-street, W.

"CANCER HOUSES."

BY A. HAVILAND, M.R.C.S. ENG.

MR. SAMUEL G. SHATTOCK in his Morton Lecture, delivered at the Royal College of Surgeons of England on May 3rd, 1894,¹ after stating that my conclusions, drawn from my collection of statistics in England and Wales, "were that cancer was most prevalent along the courses of rivers which seasonally flood their banks, and especially where, from the flatness of the country, the floods were retained; the districts about the Thames and Severn and Mid-Devon and Yorkshire rivers were especially noteworthy."² went on to remark: "But there were lesser areas where the endemic character was still more highly pronounced. The best of such was that described by Mr. Law Webb in his paper on the *Etiology of Cancer*.³ Mr. Shattock then briefly gave an abstract of the cases reported by Mr. Webb, which through his kindness I am enabled to give in full. Mr. T. Law Webb, after referring to my views and my statement "that a study of the Registrar-General's returns shows the existence of 'cancer fields' and 'cancer areas' in this country, and that soil and situation have much to do with the mortality from this disease," adds: "I would go further and suggest that there are 'cancer houses' and cancerous water or water-supplies." "I shall quote," he writes, "a series of cases bearing upon these questions. It will be noted that I assume one cause for all the various forms of carcinoma. This is not postulating too much, for could there be diseases more widely differing from each other clinically than lupus, phthisis pulmonalis, and pulpy disease of a joint, which are all, nevertheless, acknowledged to be due to the presence of a single irritant, the tubercle bacillus? And I fail to see why scirrhus, rodent ulcer, epithelioma, or any other forms of carcinoma may not proceed from one and the same cause, whatever that may prove to be.

"CASE 1.—In a village not two miles from my residence are two houses under one roof, with a drain system and water-supply common to both. I will call these dwellings No. 1 and No. 2. Twenty-six years ago a man aged twenty-eight, living at No. 1, suffered from cancer of the rectum, of which he died. The diagnosis was confirmed by examination post mortem. The house was next occupied by Mr. J. M— and his wife. This gentleman, aged about sixty, two years after the death of the previous tenant was treated for cancer of the stomach, of which malady he died after three months' illness with constant vomiting. His widow continued to live in the same house, and died ten years later, aged sixty-five, from cancer of the rectum. A mass of tumour substance protruded externally before she died. She was ill about six months. Before her death, however, Mrs. B—, aged fifty, who resided next door at No. 2, was found to be suffering from cancer of the breast, which proved fatal in eight months. After the death of Mr. J. M—'s widow No. 1 was occupied by three maiden ladies. Of these, Miss P— died four years ago from cancer uteri at the age of fifty-eight. She was assiduously nursed by Miss F—, who also died last winter with all the symptoms of cancer of the stomach; her age was sixty-one. The other lady still survives in fairly good health. None of these people were blood relations, nor can I discover that any of them had a family history of cancer. This is therefore a remarkable sequence of carcinoma cases; and in my limited research into the literature of the subject I have met with nothing like it.

"CASE 2.—In a group of cottages much nearer to my house nine cases of cancer have been treated in the past fifteen years. These dwellings are grouped together and do not occupy much more than an acre of ground. All the inhabitants use water from a certain pump situate by the roadside and close to a filthy hovel. There are twenty houses in all; one cottage enjoying a bad pre-eminence for dirt and discomfort furnished three cases of cancer out of the nine mentioned above. In order to enter this hovel one has to stride across a small cesspool in front of the door-step. Here eight years ago lived an old man with epithelioma

of the lower lip. I removed the growth and was disappointed to find that no sooner was the operation wound healed than difficulty in swallowing was noticed, and in about four months he died of malignant stricture of the gullet. His widow continued to live in the same cottage, and so also did a male lodger who had been with the old couple some years. This old fellow, a hardy, healthy looking old man of sixty, working as a road maker, came to me two years ago for the removal of an epithelioma of the lower lip. This I excised, and he remains well so far with no recurrence of the growth. The widow, however, last year consulted me about a sore in the skin of her back over the sacrum, which troubled her greatly. It spread slowly and would not heal. Though it looked more like a patch of lupus than anything else I strongly advised excision. This was eventually done in a thoroughly effectual manner by Mr. Barling, and up to the present time there has been no recurrence. Microscopic examination of the growth leaves no doubt as to its nature, as it has the usual structure of epithelioma. It will be noted that these three cases were not related; nor were any of the remaining six cases akin. In no one of the nine was there a family history of malignant disease.

"CASE 3.—I will quote but two more instances of what I have called 'cancer houses.' In one a domestic servant suffered from cancer of the breast in 1864. Many years after a gentleman who had long lived in the same house died of cancer of the bladder in 1890.

"CASE 4.—In the other an elderly man died eighteen years ago from cancer of the rectum. He was at one time under the care of Mr. Furneaux Jordan, who confirmed the diagnosis already made of malignant disease. Eight years ago his wife also died of cancer of the rectum. She had continued to reside in the same house."

In a subsequent paper on "Endemic Cancer," published in October last,⁴ Mr. T. Law Webb adds this note to Case 3:—"A lady who has for many years paid an annual visit to this house, staying some weeks on each occasion, tells me that her maid, who always accompanied her on these visits, died in 1893 from cancer of the uterus. It is singular that the inhabitants of this dwelling do not drink the water from their own pump on the premises. For some reason not very evident they prefer the water from a pump situated close to a row of old cottages four hundred yards lower down the valley. In these cottages I attended a woman with cancer of the breast in 1875, and another with cancer of the uterus in 1885. The pump is close to the houses, and not far from the cesspool." Following this note Mr. Webb gives some additional illustrations.

"CASE 5.—In 1868 a maiden lady, living at No. 5 in a terrace in which were five houses, died from cancer of the breast. Her brother, who had formerly lived at No. 1, kept a public-house two miles away. He died from cancer of the mouth. His widow continued the business for some years and then retired, coming to reside in the above-mentioned terrace at No. 1. She died soon after from cancer of the uterus, in 1884.

"CASE 6.—An accountant in a village near here died from cancer of the breast in 1869; his housekeeper died in the same house from cancer of the stomach in 1885; and in the year 1894 the gentleman who succeeded to the duties of the deceased accountant succumbed to cancer of the tongue complicated with disease of the lungs. He occupied the same rooms as his predecessor. The water used in this house comes from an open well by the roadside.

"CASE 7.—The wife of an ironworker died from cancer of the uterus in a certain row of cottages in 1867. The man soon married again, and continued to live in the same house ten or twelve years. He then moved to a house nearer to his work, where he soon after died from heart disease. His widow died in 1892 from cancer of the uterus. The water used for drinking, in the row first mentioned, was a mixture of surface water and spring water from a roadside spout.

"CASE 8.—A patten-maker died in 1875 from cancer of the rectum; his widow died in the same house, also from cancer of the rectum, in 1884; and a daughter who had lived for many years with these old people died from cancer of the breast in 1888. Drinking water was obtained from a pump a few yards from a cesspool.

"CASE 9.—A labourer, who lived in a block of houses near to the Severn, died in 1876 from cancer of the rectum. His widow died in the same house in 1877 from cancer of the bladder. In this case the diagnosis was confirmed by a

³ Birmingham Medical Review, vol. xxxii., December, 1892.

⁴ Ibid., October, 1894.

post-mortem examination. The water used for drinking by these people was from a roadside well half a mile distant.

"CASE 10.—In 1885 a furnaceman died from obstruction of the bowel of an obscure kind. A post-mortem examination revealed the presence of a button-shaped mass of carcinoma in the sigmoid flexure of the colon and also secondary growths in the anus and perineum. He died in one of two cottages forming a single building lying back from the road in a garden. In 1893 a woman died in the other cottage from cancer of the uterus. Both these houses use water from the same well, which is near the privy. There is no drainage whatever. A cesspool receives everything, and is emptied once in five or six years."

I consider the above cases to be so interesting, and so typical of what probably is taking place more or less all over Great Britain, that I am anxious to call the attention of the medical profession to them, and especially that of my fellow workers in this investigation. With regard to the possibly polluted water-supply in those cases I may refer your readers to what I have already published in THE LANCET.⁵ I may remark that I did not read Mr. Shattock's Merton Lecture until August, when I at once communicated with Mr. T. Law Webb, who readily placed at my disposal all the particulars of the localities in which his cases occurred. At that time I was engaged in the investigation of cancer in the catchment basin of the river Wey in the Farnham district of the Thames basin, and had just unearthed one of those "cancer houses" which I have long had reason to believe contribute their share towards keeping up the endemic character of this class of malignant diseases, especially when situated in favourable conditions.

CASE 11.—In a hollow ("bottom") on the border land of Surrey and Hampshire, where one of the tributaries of the river Wey—formed by the springs issuing from the point where the lower green-sand (Hythe beds) rests on the Atherfield clay, and on which lies the wealden clay—for a short time forms the county boundary until it is lost in Frensham Pond, there stand a few cottages, in one of which there has been a succession of cases of cancer. This hollow, or "bottom," is one of several which flank the lower green-sand ridge and its spurs that culminate in Hindhead Hill (895 ft.). The part of the "bottom" on which the cottages stand is about 390 ft. above sea level and is enwalled by heath, heather, and bracken-covered ridges of greensand rising to between 500 ft. and 600 ft. within a radius of half a mile. The upper part of the "bottom" is comparatively dry, but as one descends and approaches the 450 ft. level the soil gets damper, until alders, rushes, and moss are met with growing luxuriantly, and everything apparently sodden. The house in which the cases occurred stands about 20 ft. above the stream (which sometimes floods its banks), and is not now occupied, as a new one has been lately built close by. A man aged sixty-eight, to whose case from the old house my attention was first drawn, contracted epithelioma of the lip and died in the opposite "bottom," to which he had migrated a few years ago. He informed me that his grandmother first died from cancer, then her son, and, thirdly, her grandson, his cousin, all of whom had been operated upon but died. He then contracted the disease whilst living in the same house where the others lived and died, but he subsequently left his native hollow and lived in one on the opposite side of the ridge, where he died last summer. The river Wey, which waters Farnham and Frensham, floods its banks at times in many places; and coincident with this fact is the high death-rate in the Farnham district from cancer among females at and above thirty-five years of age.

In addition to the above cases I find two others reported from France. Dr. S Duplay, professor of clinical surgery at the Medical Faculty of Paris, and Dr. Cazin, chief of the laboratory of the Charité Hospital, in their lectures on the Contagiousness and Inoculability of Cancer,⁶ refer to the two following cases:—

CASE 12.—Dr. Kiessinger has reported the occurrence of a veritable epidemic of cancerous disease in a group of three houses at Oyonnax, where four cases of cancer came under his personal observation in the space of four years. In all four patients the affection could apparently be traced to contamination with the dressings from a case of scirrhus of the breast.

Several instances of "house epidemics" of cancer have been collected by Dr. O Guelliot of Reims, some of which were observed by himself and the rest by various writers.

CASE 13.—Dr. Fabre has also published a number of original observations, including one by Dr. Lambert Mollière of a series of four cases of cancer occurring in less than ten years among the occupants of a house under circumstances which, according to the observer, preclude all possibility of a mere coincidence.

Dr. Duplay concludes by stating that "the evidence in this direction is not sufficiently conclusive to permit of a definite opinion. I shall therefore dismiss the subject without further discussion. The facts above enumerated appeared to be worth mentioning, if only because they confirm Professor Metchnikoff's hypothesis (in favour of the peptospermal theory) that cancerous neoplasms might possibly belong to a group of miasmatic diseases capable of being propagated by spores formed outside the organism."

I believe with Mr. T. Law Webb that if such cases were more thoroughly sought after and recorded than they hitherto have been much light would be shed not only upon the etiology of cancer, but upon the causes that promote its increase and extension, a knowledge of which in the sequel may lead to the enforcement of greater caution in the treatment of this class of malignant diseases.

PHYSICIAN TO THE ST. PANCRAZ AND NORTHERN DISPENSARY;
PHYSICIAN TO THE INFIRMARY FOR DISEASES OF THE CHEST
AND THROAT, MARGARET-STREET; AND PHYSICIAN TO
THE FINCHLEY DISPENSARY.

INDIGESTION, either as a primary disorder or secondary to some other departure from health, notably in tuberculosis, is so frequent a symptom among hospital patients, and when left untreated is productive of such marked deterioration in the general health, that one is tempted to try with an open mind remedies which appear to possess properties likely to restore the functional activity of the digestive apparatus, or which at least will do the work which nature, handicapped by the fact that part of the machinery is out of gear, leaves undone. Among the digestive ferments there is one which apparently possesses properties peculiar to itself, one, moreover, which is stated to produce its effects under conditions less rigidly defined than pepsin, in that it converts proteids into peptones in either an acid or alkaline medium. Inasmuch as this indifference to the reaction of its medium enables the drug to continue its action in the intestines after leaving the stomach, one is justified in anticipating that satisfactory results might be obtained in cases in which pepsin fails to attain the object in view, which is, of course, complete gastro-intestinal digestion. These considerations have led me to employ Finkler's papain—for this is the digestive agent I refer to—somewhat extensively during the past year in the treatment of various forms of dyspepsia. The results on the whole have been so satisfactory that I think a brief account of some of them may be deemed worthy of publication. I have before me the record of some fifty cases in which I have prescribed papain. By far the greater number of these patients were young women and girls who were suffering from atonic dyspepsia as a troublesome concomitant of amenorrhœa, neuralgic dysmenorrhœa, menorrhagia, incipient phthisis, and some forms of hysteria, and in nearly all my success with the drug has been most marked and rapid. The other cases in which I gave papain were those of patients suffering from the dyspepsia of a more advanced stage of phthisis, from chronic bronchitis, and valvular disease of the heart. Here, too, I usually succeeded in alleviating the symptoms directly referable to the digestive trouble, which, of course, was all I was entitled to hope for. I append brief notes of twelve cases picked out almost at random principally from my outpatient records. It will be observed that where benefit ensued from the use of the drug the improvement was, as a rule, unmistakable after the ingestion of the first dose or two.

CASE 1.—A pallid woman aged twenty-one years, with waxen complexion, came under my care in September, 1893. She had enlarged and flabby tonsils, and complained of pain in swallowing together with general languor and debility. Her menses were regular, but profuse and painful. Her throat trouble soon yielded to simple treatment by chlorate of potash and hydrochloric acid, and she took iron (principally in the form of ammonio-citrate) until Sept. 14th, 1894, with

⁵ Increase of Cancer, its Probable Cause, THE LANCET, Aug. 9th, 1890.

⁶ The Medical Press, Jan. 16th, 1889, pp. 58-59.

considerable benefit to the general health; but at this date she complained of pain in the epigastrium coming on almost immediately after meals and after taking the medicine. She was also constipated. I ordered one grain of papain, five minims of dilute hydrochloric acid, and chloroform water to one ounce, to be taken three times a day after meals, together with five grains of aloes and iron pill to be taken every night at bedtime. The relief was immediate and marked, and she has complained of no dyspeptic symptoms since. The anæmia is steadily improving and she is still continuing the treatment.

CASE 2.—A young woman aged nineteen years, first seen on Aug. 4th, 1894. She was anæmic and complained principally of pain and flatulence coming on almost immediately after meals, with occasional waterbrash. Menstruation was regular, but had been painful and excessive. I prescribed a mixture of subnitrate of bismuth with bimeconate of morphine, which I afterwards supplemented with Bland's pill. She did not appear to derive any benefit from this treatment, so on Sept. 1st I put her on papain with hydrochloric acid and gentian, continuing the Bland's pill. The pain was much relieved after a few doses, but the flatulence and waterbrash did not entirely leave her until Oct. 6th. She is now quite free from dyspeptic symptoms, and her general condition is steadily improving except in respect of the menstrual irregularities, which continue to give her trouble.

CASE 3.—A woman aged twenty-two years came to me on Sept. 16th, 1893. She was by occupation a seamstress, and worked about eleven hours a day. She was pale and thin, and complained of intense pain at the epigastrium, coming on shortly after a meal and lasting for more than an hour. She said she thought she had been losing flesh for some time past. The menses were normal; the bowels were confined. Auscultation revealed dullness over the right apex, with bronchial breathing, bronchophony, and some rather fine crepitation, but she did not cough much, her principal troubles being those referable to the dyspepsia. She obtained passing relief from a bismuth mixture, and was then put on the ammonio-citrate of iron, when the dyspepsia straightway returned, not being relieved this time by bismuth. I then prescribed papain with dilute hydrochloric acid, which gave her immediate relief, and this treatment she is still under, with the addition of five grains of Bland's pill twice a day. Her digestion is now accomplished without any trouble, and she has increased in weight. Her lung trouble remains about the same.

CASE 4.—A young woman aged nineteen years came under observation on Nov. 24th, 1894. She said her life was made a burden to her by the periodical recurrence of pain in the stomach supervening immediately after meals, lasting about an hour and accompanied by flashings and heartburn. The appetite was variable, being sometimes almost in abeyance and sometimes ravenous, but at present very poor indeed. She was markedly anæmic, with a small pink spot on either cheek. The chest sounds were normal, menstruation was regular, and the bowels regular. I ordered her one-grain doses of papain with hydrochloric acid and gentian, to be taken thrice daily after meals, with five-grain doses of Bland's pill twice a day. At her next visit she reported herself as much better, the pain and heartburn having ceased to trouble her almost with the first dose of the medicine. She no longer becomes flushed after meals, and the appetite has improved. She has asked to be allowed to continue the treatment.

CASE 5.—A young woman aged eighteen years came to me on August 25th, 1894, with a history of having felt languid and unwell for five or six months, with pain in the epigastrium coming on half an hour after food and lasting an hour. There was no vomiting. The menses had never been regular, and she had seen nothing for over two months. The bowels were constipated. I ordered the usual dose of papain with acid thrice daily, with a ferruginous pill. I saw this patient again on Sept. 1st, when she stated that the pain in the stomach had quite gone, having markedly improved after the first dose. On Sept. 15th she reported herself as "ever so much better." She has not returned since that date, so I presume she considers further treatment unnecessary.

CASE 6.—A young woman aged nineteen years came to me on Sept. 1st, 1894, complaining of acid vomiting coming on half an hour after taking food, unaccompanied by pain. This state of things had lasted upwards of three months, with the result that she had been gradually getting thinner. The appetite was commonly ravenous. The menses were fairly regular, but profuse. I detected nothing abnormal in the

chest, but she looked pale and pinched. I ordered papain in one-grain doses, with acid. When I saw her again on Sept. 8th she told me the vomiting had ceased at once after taking the medicine; in fact, the dyspeptic symptoms for which she had consulted me now troubled her so little that she was anxious to be given a tonic. Under a mixture of ammonio-citrate of iron, however, all the symptoms returned in an aggravated form, and she came back begging to be put back on the old medicine. The papain again gave her almost immediate relief, and she continued the treatment until able to dispense with its assistance.

CASE 7.—A somewhat emotional woman aged twenty-five years, subject to mild attacks of hysteria, had suffered from "pain over the heart," increased after meals, for three months in July, 1894, with flatulence and eructation. She menstruated every three weeks. The bowels were irregular. The lungs were normal on auscultation. The heart's action was rapid, but there was no evidence of valvular mischief. Under papain and Bland's pill she professed to be improving greatly (and she certainly looked much better), when on Oct. 20th she came back in a highly hysterical condition and said she was very much worse. I ordered her a mixture of bromide of potassium and valerian and have not seen her since. She was certainly improving under the papain, but the hysterical element rendered her a very unsatisfactory patient to deal with.

CASE 8.—A woman aged fifty-eight years came to me in July, 1894, with a history of Graves' disease extending over ten years, which had been aggravated by an attack of influenza the previous Christmas. For the last three years she has had more or less oedema of the ankles. Her principal complaints now were palpitation of the heart and vomiting directly after the ingestion of food. She was markedly cachectic and there was slight general enlargement of the thyroid gland. Proptosis was very marked. The lungs were fairly normal, but the heart was rapid and most irregular, with an occasional intermission; there was no murmur. I ordered papain with hydrochloric acid and digitalis, under which the vomiting promptly ceased. She improved in many ways until Oct. 31st, when, the stock of papain being temporarily exhausted, I ordered a bismuth mixture to go on with. The urgent vomiting returned, and at her next visit she begged to have her old medicine. This afforded the desired relief and she is still continuing the treatment.

CASE 9.—A woman aged twenty years came under my notice on Sept. 24th, 1894, and complained that for three months past she had been troubled with pain directly after taking food, so intense that she was afraid to eat. The menses were every fortnight, sometimes scanty and sometimes profuse. The chest sounds were normal. Her aspect was very anæmic. In this case papain with aloes and iron pill failed to give relief, so a week or so later I gave her some bismuth and bimeconate of morphine, under which she is improving at the present time.

CASE 10.—A young woman aged eighteen years came to me on Sept. 29th, 1894, complaining of pain at the epigastrium coming on after meals and running through to the back between the shoulder-blades. She felt sick, but did not actually vomit. She was very anæmic, and the menses, though regular, were scanty. The pain absolutely disappeared after the first dose or two of papain, and she improved so much that in a short time she felt well enough to discontinue the treatment.

CASE 11.—A woman aged twenty-four years had been under treatment for anæmia off and on ever since she was nineteen, in addition to which she suffered from dysmenorrhœa and constipation. She was never satisfied with any medicine for long together and would often disappear for several weeks or months and give some other institution a turn. On Nov. 7th, 1894, she came complaining of frightful pains after meals, not accompanied by vomiting, and she looked very pale and ill. I ordered her a mixture of papain. At her next visit she looked much better and grudgingly admitted that the pain was better after taking the medicine. I lost sight of this patient, so I am unable to say whether permanent benefit followed the treatment.

CASE 12.—A woman aged twenty years came to me on Nov. 20th, 1894. She said that since an attack of influenza a year ago she had been troubled with a cough with scanty frothy expectoration. There had been one attack of slight hæmoptysis five months ago. Menstruation was regular, but scanty. The bowels were regular. The appetite was poor. Of late she said she always felt sick after food and often

vomited. Her mother died from phthisis. Nothing abnormal could be made out on auscultation of the lungs, but the heart's action was rapid and heaving, and there was a slight systolic murmur at the apex conducted outwards. In order to relieve such of the symptoms as were referable to the stomach I ordered her a mixture of papain, and the vomiting forthwith ceased. She is still under treatment.

CASE 13.—A man aged fifty-one years came on Sept. 15th, 1894, complaining principally of pain and vomiting after meals, from which he had suffered off and on for seven years. There was some consolidation at the apex of the left lung. The vomiting ceased at once under papain, though the pain did not entirely disappear under the treatment. I then combined small doses of morphine with the papain, under which the pain and other symptoms disappeared, and he was soon enabled to discontinue his attendance.

I have chosen these cases pretty well at random in order to show in what instances papain did good and also those in which it either did not afford relief or had for some other reason to be discontinued. In uncomplicated cases of atonic dyspepsia papain appeared to exert very beneficial effects, and in the instances in which this was the case I was struck by the almost immediate relief thus obtained. In only three cases in which I have prescribed the drug did it apparently fail, but in two of these (Cases 7 and 9) the patients were emotional women in whom the dyspepsia was associated with subjective symptoms of a hysterical character. The third case was that of a man aged forty-six years, an alcoholic, who suffered from dyspepsia with waterbrash, which yielded to bismuth.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF DIABETES INSIPIDUS.

By ROBERT J. LEE, M.D. CAMB., F.R.C.P. LOND.,
LATE PHYSICIAN TO THE HOSPITAL FOR CHILDREN, GREAT ORMOND-STREET.

A YOUNG woman nineteen years of age was for many years the subject of diabetes insipidus. The malady was attributed to a fall from a hayrick when she was about four years old, and up to the time when she had the attack about to be described, which occurred last June, there was nothing unusual to record. The chief trouble during those years was thirst, particularly during the night, which led to the drinking of between three and four quarts of water after going to bed and getting up in the morning. The illness, which commenced in June, followed immediately after exposure to the strain of an examination, and retention during some hours, without permission to leave the room, caused great suffering each time it occurred. Great weakness followed immediately; the symptoms of diabetes ceased, and there was no thirst during the night. When the case came under the care of my friend, Mr. James Kingston Barton, the great state of prostration and feverishness led to the suspicion that this was some form of remittent fever, and soon it was considered proper to report the case to the medical officer of the parish. The skin was highly congested, the pulse quick, and the temperature, when Mr. Barton first took it, in the morning was 102.5° F. and in the evening 104.5°. It continued like this for a week and then fell for a fortnight two degrees morning and evening. Then it rose three degrees—that is, to 103° and 105°—for a week, and fell again lower than it was before. In this way from June 22nd to Aug. 22nd the state of fever continued without any symptoms of intestinal disorder or of other serious nature except attacks of nasal hemorrhage so violent as to cause great alarm. During the next month a gradual fall of temperature to the normal took place, and gradually the night thirst returned, so that by the middle of September there was nothing to note except great prostration and not enough strength to allow of the patient being moved to the seaside till some weeks further had passed. By degrees during the winter the patient's strength has been restored to some extent, but not entirely to its former state, and the case seems to deserve notice in the interest of those who may be exposed in examinations at

schools, where such easily prevented accidents are possible. So far as treatment deserves notice, it may be remarked that no effect seemed to be satisfactory, and that not until the symptoms of returning diabetes displayed themselves did there appear to be any sign of improvement. It is strange to have a person in whom the healthy condition of the kidneys is one favouring excessive secretion of urine, and that any interference with this action is liable to serious constitutional disturbance. If this case recalls similar cases to others it would be interesting if they were recorded, and would help us to comprehend the curious and inexplicable phenomena that appear in diabetes in its various forms.

West Kensington, W.

SWALLOWING OF A PIN BY A CHILD.

By JAMES TILLY, M.D. ST. AND., L.R.C.P. EDIN.,
M.R.C.S. ENG.

INSTANCES of a pointed metallic body passing harmlessly through the alimentary tract are sufficiently unusual to justify the publication of the following case. A child aged five years having swallowed a pin on the evening of Nov. 21st, I directed that solid food, such as rice pudding &c., should be taken, and also gave a mixture containing tincture of opium, tincture of lavender, and chloroform water. On the evening of Nov. 23rd the pin was voided per anum, firmly packed in a solid cylinder of feces, having consequently traversed the alimentary canal in forty-eight hours. It may be described as a small scarf-pin, having a total length of almost an inch and a half. The head is circular, flat, very thin, and nearly three-eighths of an inch in diameter; the stem is of brass, slender, and very sharp, and its upper part is bent so that the stem is parallel to the plane of the head. The diagram gives a good idea of the size and shape of the pin.

Chiswick.

ON ABSORBENT DRESSINGS, ASEPTIC AND CHEAP.

By ARTHUR NEVE, F.R.C.S. EDIN.,
SURGEON, KASHMIR MISSION HOSPITAL, INDIA.

FIFTEEN years ago there was no consensus of opinion with regard to the best materials for surgical dressings. Listerism was introducing everywhere the use of gauze with mackintosh outside. Gamgee and others were working with absorbent material, whilst tow and ordinary cotton-wool were the staple dressings elsewhere, and carbolic oil the favourite application. As a rule the dry dressings were not aseptic, and the antiseptic dressings were not dry. The introduction of medicated absorbent cotton-wool and wood-wool reconciled these two methods; gauze dressings have also been used dry for many years, and many of the old crude applications have been banished, so that in the hospitals of Europe the same cardinal principles are everywhere recognised and to a great extent the same materials adopted. It may be assumed that surgeons are now satisfied with the ample choice of sterilised or antiseptic and absorbent gauzes or wools, but that managers of hospitals and war officials are less content with these changes, which have involved "an altogether astounding increase in expense." The question of cheapness cannot be altogether set on one side. It is not a question of antiseptic *versus* aseptic surgery, but of *cheap versus expensive antiseptic* appliances. The French War Department has adopted peat as the best cheap absorbent dressing. Peat-moss appears to have been used successfully in Russia for the last ten years. Suggested by Leisrink, it was soon used by Schede, Hagedorn, and others. I tried it for a time, but soon fell back upon sawdust pads, which have now been our staple dressing material for over ten years. Thomas of Liverpool and others have used them in England. These have now been introduced by Surgeon-Lieutenant-Colonel Lawrie into the hospitals and dispensaries of Hyderabad State. They are cheap. In Kashmir sawdust costs about sixpence a hundredweight. The muslin bags can be made at the rate of about 500 for £1. They can be made aseptic or antiseptic. We impregnate the pads the day before use with a 1 in 2000 solution of mercuric zinc cyanide. They can be easily

sterilised in a Cathcart's or Schimmelbusch's oven. They are absorbent, but not too drying. Surgeons who have used moss have found it too drying, as the discharges crust underneath it, and the moss needs damping from time to time. Sawdust pads will absorb twice their own weight of pus or serous discharge. Absorbent wool frequently allows a small amount of discharge to penetrate to the bandages. This seldom happens with well-adjusted pads. They are exceedingly light and comfortable and, if well made, adapt themselves to the shape of any surface. The sawdust should not be too fine or the muslin too coarse.

OF

HOSPITAL PRACTICE BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

THE following cases under treatment at St. Thomas's and St. Mary's Hospitals illustrate difficulties which may occasionally arise in making a correct diagnosis as to the nature of a tumour in the renal region. Hepatic enlargements on the right side, splenic enlargements on the left, ovarian tumours, or accumulations of fecal matter in the large bowel—these are well recognised as sometimes closely resembling renal tumours, and the surgeon remembers them as conditions to be eliminated in coming to a true opinion as to the exact seat of the tumour. The symptoms produced by some other growths in the lumbar region are shown by these cases as well as by those under the care of Mr. H. Morris which we publish at p. 1047.

ST. THOMAS'S HOSPITAL.

A CASE OF CARCINOMA OF THE LEFT KIDNEY OF UNUSUAL DURATION; NEPHRECTOMY; RECOVERY; REMARKS.

(Under the care of Mr. WILLIAM ANDERSON.)

THE history of an enlargement noticed for six years in the region of a kidney which proved to be the seat of a carcinomatous growth is unusual, more especially as hæmaturia, one of the most characteristic symptoms of such a disease, was absent throughout. As regards removal of such growths of the kidney, Mr. Greig Smith¹ writes: "In all cases where the disease has been known to exist for some months, where the growth is large, and more particularly if it is firmly adherent in the loin, no operation is advisable. In a word, for malignant disease nephrectomy is a justifiable procedure only in a few specially selected cases." In this patient there appeared to be no evidence of secondary growth, and the result of the operation fully justified the removal of the kidney. We are of opinion that statistics of the operation of nephrectomy for malignant disease would show a greatly diminished primary mortality at the present time. The case to which Mr. Anderson draws attention in his remarks is one which shows the close resemblance between a malignant growth of the large bowel in front of the kidney and a tumour of the kidney itself. The difficulty thus caused in coming to a correct diagnosis does not often present itself in actual practice, but should be borne in mind. It would be very much increased if a renal growth had extended into the overlying bowel and produced destruction of its wall. Such a case has been recorded by Dr. Peacher;² there was extensive adhesion between the tumour (a primary hard carcinoma) and the colon, with numerous perforations of the latter, allowing of the escape of fecal matter into the peritoneum. For the notes of this case we are indebted to Mr. Finch White.

The patient, a woman aged fifty-one years, was admitted into St. Thomas's Hospital on Jan. 3rd last, with a tumour

on the left side of the abdomen. The growth was first noticed six years ago (nine months after the birth of her last child) as a painless prominence of the size of a fowl's egg, situate near the level of the umbilicus. She had lost flesh during the few previous months, but remained fairly strong, and had suffered from no functional disturbance except a slight cough with occasional expectoration of a little bloodstained mucus. There was a family history of strong tuberculous predisposition, but none of malignant growth. On admission she was a tall, thin woman, somewhat emaciated, but showing no sign of prostration. Local examination demonstrated a tumour of irregularly rounded outline, and about the size of an ostrich egg, projecting below the costal border on the left side; it could be traced backwards into the loin, downwards as far as the iliac crest, inwards to the median line, and above as far as the line of gastric resonance. It was dull on percussion, insensitive to pressure, and was freely movable within certain limits, but appeared to have connexions at the back of the abdominal cavity. The descending colon ran down on the outer side of the mass. The urine contained a trace of albumen, but no other evidence of visceral disease was ascertainable. It was considered that the growth was most probably renal or omental in origin, but in any case an operation was desirable. On Feb. 4th Mr. Anderson opened the abdomen through the left linea semilunaris. The great omentum was exposed, and on drawing this up the posterior parietal peritoneum and the left colic vessels were found to be tightly stretched over the tumour, while the descending colon was pushed over to the left. The colic vessels were ligatured and the peritoneum was divided, exposing a smooth, rounded, slightly lobulated growth which could be traced backwards to its origin from the upper end of the left kidney. It was carefully isolated, the pedicle of the kidney was exposed, and the renal vessels with the ureter were divided into three segments, which were ligatured separately. The whole mass was then detached and the abdominal wound closed. The supra-renal capsule was not seen during the operation, and no enlarged glands could be felt. Little blood was lost, but an enormous number of ligatures was required. The shock of the operation was rather severe but not grave, and the patient was in good condition on the following morning. The temperature remained normal in spite of an attack of bronchial catarrh until the end of the week, when a slight rise occurred. On removing the dressings a quantity of inodorous pus escaped from the lower angle of the wound. The discharge gradually ceased, and the patient left the hospital on March 24th. The tumour was pronounced by Mr. Shattock to be a carcinoma involving the upper third of the kidney.

Remarks by Mr. ANDERSON.—This was a case in which, from the position and mobility of the growth and the absence of pathognomonic symptoms, a positive diagnosis was almost impossible. Two alternative opinions as to its nature were hazarded, and one of these was found to be correct, but it would not have given rise to any great astonishment had the tumour proved to be something of a different kind. It is still somewhat difficult to reconcile its undoubted malignancy with the long history given by the patient and with the absence of indications of cachexia. The following brief outline of a second case, under treatment at the same time, serves to illustrate further the difficulty that may arise in the interpretation of local signs in this region. The patient, a woman aged fifty years, was admitted into St. Thomas's Hospital with a large oval tumour occupying the left loin and extending upwards to the area of gastric resonance and downwards into the pelvis. It appeared to correspond exactly to the region of an enlarged kidney, and this impression was supported by a marked diminution in the excretion of urea, and by the presence of a small quantity of albumen in the urine. All the other functions were normal except for an occasional attack of diarrhoea, to which the patient had paid little attention. A diagnosis of renal tumour was formed with some confidence, and it was proposed to remove the growth by a free lumbar incision. On cutting down at the back of the loin a kidney of perfectly normal aspect was exposed, and the tumour sought was felt in front of the organ. A second incision was then made in the left semilunar line and the disease found to consist of a carcinoma of the descending colon, the wall of the gut being replaced by an enormously thick mass of new growth, while the lumen evidently remained sufficiently large to allow free passage to fecal matters. The wound

¹ Abdominal Surgery.

² Sajous' Annual of the Universal Medical Sciences, 1889, G. 30.

was closed and the patient rapidly recovered. She left the hospital a fortnight later, not only none the worse for the exploration, but expressing herself as feeling much better and more comfortable than before. These examples, with many others which the experience of every surgeon can furnish, will show that it behoves the operator to approach in a tentative spirit even the cases in which he is most inclined to form a positive diagnosis, that he may be ready for any surprise, and undisconcerted in action should the conditions prove to be what he least looked for. Fortunately we may now resolve our doubts with a minimum of risk to the patient, and with a hope that the exploration, even though it go no farther, may afford a relief that science has yet to explain.

ST. MARY'S HOSPITAL.

OBSCURER "RENAL SYMPTOMS"; CANCER OF ASCENDING COLON; RESECTION; DEATH; REMARKS.

(Under the care of Mr. EDMUND OWEN.)

IN considering the diagnosis of such a case as the following it must not be forgotten that the probable mistake made occurred a year before the patient came under treatment at St. Mary's Hospital. At that time the tumour would be much less distinct and the difficulty in coming to a correct opinion much greater. This does not, however, detract from the importance of the case from a clinical standpoint, but is rather emphasised by what Mr. Owen says of the former operator. There are many other abdominal swellings which must be considered by the surgeon in making a diagnosis of movable kidney before he can feel confident that the tumour which he feels is the kidney—viz., impacted feces in the colon; ovarian tumours, especially small ones with long pedicles; tumours of the parovarium; hydrosalpinx; enlargements of the gall-bladder; deposits in the pylorus, inflammatory or malignant; tumours of the omentum; dermoid tumours of the intestinal wall; and pancreatic growths. As a rule the diagnosis is easy and the surgeon is unlikely to make a mistake; Mr. Owen's case shows the necessity of a careful consideration of the symptoms and accurate examination of the abdominal tumour. For the notes of this case we are indebted to Mr. W. D. Wiggins, clinical clerk and dresser.

The patient, a man aged fifty-five years, was admitted into the Thistlethwayte Ward of St. Mary's Hospital on last New Year's Day. He looked very worn and ill, and he remarked that he had lost four stone in weight during the past three years. He said that his troubles began about four years ago with a dull, dragging pain in the right loin, which sometimes extended across the abdomen, but generally shot down into the right groin. The pain came and went irregularly, lasting six or ten minutes and disappearing completely between the attacks. He steadily got worse, and a little more than a year ago he went into a hospital, where the surgeon under whose care he was told him his distress must be due to the fact that he had a "floating kidney," and that it ought to be cut down upon and stitched in its proper place. To this operation he said he submitted, and a long, linear scar running obliquely over his right lumbar region seemed to confirm his statement. The man further said that the very day after that operation he had recurrence of his old pains as severely as ever, and that on informing his surgeon of this he had received the explanation that the kidney must have broken loose again. The operation produced no improvement whatever. On the other hand, the pains, which were steadily increasing up to the time of the operation upon the kidney, continued to increase subsequently, so that when he applied for admission to St. Mary's Hospital he compared them to "a thousand knives." He had also been troubled with loose, blood-stained actions of the bowels. On examination a hard, tender, and circumscribed tumour could be felt deeply in the region of the beginning of the ascending colon, well above the level of the cæcum. It was hard and tender, and was evidently the starting-point of all his pains. Whilst examining this mass it was noticed that distended pieces of intestine in the neighbourhood were struggling to rid themselves of flatus, which was apparently divided up into hard, ball-like masses. Indeed, so vigorously was the peristaltic action being carried on that the gas was locked up in the segments of the bowel under such tension as to convey, at a first touch, the idea of the

balls being solid. But they were resonant on percussion, and presently changed their position or disappeared altogether. The man was given to understand that he had a large cancerous mass which was blocking his bowel, and that though in all probability it could not be removed, an operation might be performed with the view of getting the contents of the bowel beyond the blockage. On Jan. 4th a free incision was made through the right semilunar line, and a hard mass of the size of the fist was found in the colon as it ascended in the renal region. Mr. Owen proposed connecting the ileum with the colon above the obstruction, but on one of his colleagues urging that this might afford the patient but short or imperfect relief, he resected the bowel and connected the divided ends by a Murphy's button. The growth proved to be a columnar epithelioma which almost entirely blocked the colon. Below the obstruction the muscular wall of the intestine was greatly thickened, with the object of forcing onwards the liquid and gaseous contents. On the evening before his death there was a very slight escape of feculent fluid from the wound, and the conclusion formed was that the suture was not watertight. At the post-mortem examination it was found that a perforation had occurred upon the distal side of the bowel where the thin intestinal wall pressed against the edge of the button. The man was so weak, however, when the discharge was noticed that it was not considered practicable to open up the wound and examine for a leakage.

Remarks by Mr. OWEN.—I have published this case with but a brief account of the clinical details and of the operative procedure in order that I might call attention to the uncertainty which may attend the diagnosis of "floating kidney," for I assume that this man had not at any time a floating kidney. The evidence, so far as I can read it, is very circumstantial and all against such a theory. Nevertheless, that apparently was the diagnosis made before the operation by one of the most practical, scientific, and illustrious surgeons of the day. A cancer in the middle part of the ascending colon would give rise to dull aching and pains which the patient would almost certainly associate—at first, at any rate—with his kidney; and as the mass developed, and the bowel became more and more loaded and distended, the lumbar aching would increase on account of pressure upon the psoas and the lumbar nerves. This pressure would especially be felt by the genito-crural branch, and so it came about, I think, that the patient complained of pain shooting into the groin and into the region of the cord and testis. Had these symptoms been associated with blood in the urine they might have suggested the presence of a renal calculus, but there was no history of hæmaturia. Accounts as given by patients of their former medical attendants, as of their symptoms, are usually untrustworthy. It is quite possible that the operator never suggested that this man had a "floating kidney"; but the scar gives unmistakable evidence of the kidney having been cut down upon in the loin, and this, the man said, was for the relief of pains which, except in degree, were identical with those for the relief of which I unsuccessfully removed the intestinal growth. During the operation which I performed I saw nothing to suggest that the kidney was in the least likely to shift its position. My opinion was that from the very beginning the case had been one of slowly but surely advancing cancer of the bowel.

BRISTOL MEDICO-CHIRURGICAL SOCIETY. — A meeting of this society was held on April 10th. Mr. Flemming showed a patient with an Uncommon Form of Skin Disease, and a specimen of Ulcerative Endocarditis. Dr. Aust Lawrence read a paper on Backward Displacement of the Gravid Uterus, and illustrated the communication with diagrams. Dr. J. E. Shaw and Mr. Paul Bush read a paper on a case of Tumour of the Brain involving the upper portion of the superior frontal convolution in which there was loss of motor power in the left arm and leg, especially in the movements of the shoulder- and hip-joints. The patient died three weeks after removal of the growth, and at the necropsy a portion of new growth was found bulging into the longitudinal fissure. Mr. Munro Smith showed lantern slides and specimens, prepared by Dr. Davies and Dr. Dawson, of Pneumococci found in the Bladder in a case of cystitis following pneumonia. Dr. Davies showed some interesting lantern slides of Photographs of Patients suffering from Small-pox; also micro-photographs of the Bacillus of Typhoid Fever, Tetanus, and Diphtheria.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Pathological Identity of the Various Forms of Acute Septic Inflammations of the Throat.

An ordinary meeting of this society was held on April 23rd, the President, Mr. HUTCHINSON, being in the chair.

Dr. FELIX SEMON read a paper on the Probable Pathological Identity of the various forms of Acute Septic Inflammations of the Throat hitherto described as Acute Oedema of the Larynx, Edematous Laryngitis, Erysipelas of the Pharynx and Larynx, Phlegmon of the Pharynx and Larynx, and Angina Ludovici. In his introduction he fully stated the reasons which had induced him, in spite of the absence of bacteriological evidence of his own, to submit his ideas on the question of the nature of acute septic inflammations of the throat and neck to the judgment of the society. He next showed the confusion which at present existed in the nomenclature of these inflammations, and defined his own position by expressing his conviction "that the various forms of acute septic inflammation of the throat and neck, hitherto considered as so many essentially different diseases, were in reality pathologically identical; that they merely represented degrees varying in virulence of one and the same process; that the question of their primary localisation and subsequent development depended in all probability upon accidental breaches of the protecting surface through which the pathogenic micro-organism, which caused the subsequent events, found an entrance; and that it was positively impossible to draw at any point a definite line of demarcation between the purely local and the more complicated, or between the oedematous and the purulent forms." This thesis was then proved—from the clinical point of view—by the communication, in order of ascending severity, of fourteen cases in point (two of them with full notes of post-mortem examinations) which had come under Dr. Semon's observation. It was shown that from the slightest cases, the septic nature of which could well be doubted, to the most severe and rapidly fatal ones, complicated by pleurisy, pericarditis, pneumonia, peritonitis, and septic infection of the central nervous system, such gradual and imperceptible transitions were met with, and that, again, the serous forms of inflammations so insensibly passed into the purulent forms, that often the greatest difficulties occurred in correctly registering a case in accordance with the present terminology. Dr. Semon then endeavoured to draw a consistent clinical sketch of the course of these inflammations, and to explain the differences in their primary localisation and their various extensions. Next he discussed the various objections which could be raised against his views—viz.: (1) that no proof had been adduced that the milder cases given in his list were really of septic origin; (2) that the different primary localisations in these cases spoke against their identity; (3) that the variations in the fever curve also seemed to show that the individual cases were due to different pathological processes; and (4) that the fact of the exudation sometimes being of a serous, sometimes of a purulent, character from the bacteriological point of view militated against his view of the identity of the pathological process causing these different forms of septic inflammation. In answering these objections he particularly dealt with the importance of the tonsils as forming a natural portal for the invasion of the organism by pathogenic microbes, and from the bacteriological point of view showed by quotations from Jordan's papers that his ideas, revolutionary as they might appear from the clinical aspect, in reality constituted a simple clinical application of general bacteriological principles to a certain group of septic inflammations. In conclusion, he urged the necessity of a sweeping revision of our present nomenclature concerning acute oedematous affections of the larynx.

The PRESIDENT thought that Dr. Semon was not really making an advance, but was falling back on old-fashioned views which had not been departed from by some. He was prepared to go even further than him, and to say that many of these diseases were transmutable. He doubted if oedema of the larynx was the same thing as erysipelas of the larynx, but the one might develop from the other. He believed that there was a contagious form of catarrhal

laryngitis. He had seen a case of oedema of the larynx which ended fatally, and which appeared to be produced by exposure to cold, and not by exposure to septic influences. The virulence of these diseases might undoubtedly be intensified by transmission.

Dr. DE HAVILLAND HALL said that the older writers entertained the view that these affections were identical. Four years ago Dr. Semon spoke at Berlin much to the same effect as in the paper now produced, and this induced Dr. Hall to look up his cases for the past seventeen years. As the result of that search he asserted his belief that erysipelas of the larynx, phlegmonous pharyngitis, and angina Ludovici were so similar that the slight difference in their starting point was not a sufficient reason for making a different classification necessary. He recorded seven cases. The first, in a man aged twenty-one, started in the pharynx and implicated the larynx, the temperature rising to 106° F. The patient recovered and no albumen was found in the urine. The second case occurred in a man aged forty-nine, started in the pharynx, but did not involve the larynx. The patient died from pulmonary oedema, and albumen was found in the urine. In the third case, that of a female aged fifty, the pharynx was first involved and the disease afterwards extended to the larynx; albumen was found in the urine, and death occurred from exhaustion. This illustrated the old saying that when erysipelas extended internally the result was worse than when it extended externally. A man aged thirty-six was the subject of the fourth case; the disease involved the pharynx and larynx, and was a typical instance of angina Ludovici; tracheotomy was performed, but death resulted. The fifth case occurred in a man aged twenty-five; it commenced in the larynx and extended to the pharynx. There was no albumen in the urine, and recovery ensued. The sixth instance, in a woman aged fifty-four, commenced in the larynx and extended to the fauces; there was no albumen in the urine, and recovery ensued. The seventh and last case occurred in a woman aged fifty-six and involved the larynx; there were right pleurisy and pneumonia of both bases; albumen was present in the urine, and recovery resulted. All these cases presented much the same clinical picture, and he regarded them all therefore as identical.

Mr. LOCKWOOD said that much would turn upon the sense in which the term "pathological identity" was used; for identity of bacteriological invasion was not necessarily the same thing as identity of disease. In acute angina Ludovici there was a streptococcal invasion, and the same was highly probable of acute inflammation of the pharynx, larynx, and tonsils. But an acute abscess might be found in the arm due to staphylococcus aureus, and a peritonitis might exist due to the same streptococcus, but yet no one would say that the diseases in the arm and peritoneum were identical; it was necessary that there should be identity in the tissues which were attacked. In these inflammations about the neck and throat it was improbable that there was an identical bacteriological invasion in all. In one case, for instance, staphylococcus pyogenes had been found, while in other cases the presence of bacilli had not been given the prominence it deserved. Fœtor was common in angina Ludovici, and this was always due to a bacillus. In one case, again, bacilli were found which produced gas, and such a case could not be considered bacteriologically the same as those in which the streptococcus pyogenes was found. As to the tissues attacked there was the widest difference; in one case the invasion might be about the epiglottis and in another about the tissues of the neck. Though there was a clinical resemblance between these diseases, yet angina Ludovici often betrayed considerable clinical differences, due to a variation in bacterial invasion. Cutaneous erysipelas of the neck could not be described as angina Ludovici; it was very different, and the three varieties of erysipelas differed considerably amongst each other.

Dr. SHARKEY said that he agreed with the conclusions drawn by Dr. Semon from the clinical point of view. In the St. Thomas's Hospital Reports for 1892 he published three cases of angina Ludovici. The first was in a man aged thirty-four, who complained of diarrhoea, and three days later had a sore-throat. The case rapidly proved fatal, and at the necropsy lymph was found in both pleurae, and an acute inflammation with abscess was localised about the epiglottis. The second case occurred in a man aged twenty-nine, and developed equally rapidly; pneumonia supervened and tracheotomy was performed. At the necropsy an abscess was found in the

submucous tissues about the base of the tongue. The third case occurred in a man aged thirty-nine, malaise being followed by sore-throat and pneumonia, and a hard swelling developed in the upper part of the neck below the mouth. The whole of these cases were instances of acute primary suppurative cellulitis of the neck, all occurring near enough to the larynx to produce intense oedema of the epiglottis, and the infection he regarded as probably of septicæmic origin. It was necessary to define what we meant by pathological identity, whether it referred to the question of some definite tissue being involved or to the localised or generalised nature of the disease. He thought on the whole that this clinical group of cases resembled each other as much as did examples of any one disease in other organs.

Mr. BUTLIN said that the subject, which was sufficiently complicated before, had been made still more so by the paper. The assertion was that these diseases were all septic and that they were identically the same disease. Mackenzie in his work had already included these affections with the exception of Ludwig's angina under one head, and with regard to Ludwig's angina no accurate description of it existed. There was no sufficient proof in the paper that these diseases were identical either in their appearances, their physical structure, their clinical characters, or their pathology. In a case like that of erythema nodosum we could be sure of the identity of the disease in different individuals; epithelioma also we could recognise from its clinical appearances and its structure. Tuberculosis differed enormously in its clinical characters, but its identity could be verified by the discovery of the anatomical tubercle coupled with the peculiar bacillus. In the diseases proposed to be classed as identical very few bacteriological examinations had been made and very few inoculation experiments performed. Then the paper quoted observations to show that no less than ten microbes might produce the same pathological condition and ten conditions might be the result of the action of one microbe. Though he had hoped that order and harmony might be evolved out of the group of conditions brought together, he was bound to admit with profound sorrow that after hearing the paper he was more confused than ever.

Mr. HARRISON CRIFFS said that he sympathised with Dr. Semon in his desire for uniformity, but he could not admit that that goal had been attained. Many different pathological conditions might produce a similar affection. He referred to a case, under the care of the late Mr. Luther Holden, in which the patient suffered from gangrene of the thumb of the type of the acute septic gangrene of Larrey. The arm was amputated and the patient at first did well, but three days afterwards the throat began to swell. The swelling attained very large dimensions and was covered with black patches, and was evidently due to the same cause as the gangrene of the thumb, and in both parts of the body gas was developed in the tissues. Death ensued after twenty-four hours from suffocation. In the second instance a child had suffered from facial erysipelas, but had got well. A few days later the mother was taken ill with sore-throat; the swelling increased rapidly, and she died from suffocation. The cause in that instance was undoubtedly erysipelas. In other parts of the body we might meet with swellings produced by different causes, and the neck was no exception to this rule.

The debate was adjourned till the next meeting.

MEDICAL SOCIETY OF LONDON.

Serous Plevritic Effusion treated by Multiple Tapping and afterwards by Incision.—Sclerema Neonatorum ending in Recovery.

An ordinary meeting of this society was held on April 22nd, Dr. COUPLAND, Vice-President, being in the chair.

Dr. S. WEST related a case of Serous Plevritic Effusion of eighteen months' duration for which the chest was tapped thirty-seven times and the side then incised, the result being complete recovery with full expansion of the lung and but little flattening of the side. The patient was a woman aged thirty-one years whose illness dated from September, 1891, fluid being diagnosed in January, 1892. In June, 1893, when Dr. West first saw her, he immediately tapped the abdomen and the fluid did not return. He next tapped the pleura, and ninety ounces of serous fluid were removed by a syphon tube, the lung expanding freely, which was remarkable considering that it had been compressed by the fluid for eighteen months. The tapplings were continued at frequent intervals

for nearly twelve months, and the operation was performed thirty-seven times in all, the fluid remaining serous throughout. He hoped to complete the cure by paracentesis alone, but the patient's friends became impatient, and at last he had to consent to the side being laid open. An empyema of course developed. The fever became hectic, the patient rapidly lost flesh and strength, and soon was as ill as when he first saw her. It seemed hopeless to look for her recovery, but when at her worst she suddenly began to mend without any obvious reason, convalescence gradually set in, and from this time was uninterrupted. The points of interest in the case were (1) that after the side had been full of fluid for twelve months and more the lung should not be bound down, but should be capable of rapid re-expansion; (2) the number of times that the side was tapped and the probability that complete cure might have been obtained in this way; (3) the fact that after thirty-seven tapplings the fluid remained clear and serous as at the first, and that, too, in spite of air having been admitted more than once into the pleura; (4) the opening of the side for a simple effusion; and (5) the ultimate complete recovery with practically no deformity and perfect re-expansion of the compressed lung.—Dr. DE HAVILLAND HALL referred to a case which he brought forward, together with Mr. Goodsall, two years ago. Tapping was resorted to thirteen times, and 705 fluid ounces of clear fluid were drawn off altogether; the patient recovered. As there was a syphilitic stricture of the rectum it was thought that the lesion of the pleura might be syphilitic also. Up to the present time he had made up his mind that he would not open a case of simple serous effusion, and he would even go beyond thirty-seven tapplings before doing so; the precarious condition of Dr. West's patient after the opening of her chest still more fortified his opinion and confirmed his fears.—Dr. ROUTH remarked that the opening of the abdomen in tuberculous disease had proved to be curative, and he did not see why this should not prove to be equally true with regard to the lung.—Dr. COUPLAND remarked that the case appeared to be unique. Could it be strictly called inflammatory? The cause of the effusion might be a local one and due to some local disturbance of the circulation. In an obstinate case of clear serous effusion into the pleura he had resorted to opening the chest, and this was followed by very serious symptoms for a time, but ultimately recovery ensued.—Dr. WEST, in reply, referred to the strong family history of tuberculosis in the case. There was a history of acute onset, and the case was one that would have commonly been classed as an inflammatory effusion. He did not think that empyema could set up tubercle, but that interference in tuberculous subjects frequently led to the development of acute tuberculosis. As most cases of tuberculous peritonitis got well by tapping it was unnecessary to resort to opening the abdomen.

Dr. ARCHIBALD GARROD then read a paper on a case of Sclerema Neonatorum ending in recovery. The patient was a male infant first seen by Dr. Garrod at the age of five weeks. At birth induration was noticed upon the buttocks, and had extended until it covered the entire back and involved the dorsal aspects of the upper arms and thighs. The indurated area did not pit on pressure; the outline was sharply defined and maplike. There was pink mottling in places. The legs could not be fully extended either at the hips or thighs, and in the popliteal spaces there was a well-marked hidebound condition. The infant was otherwise in good health, and slept and took the breast well. There were no signs of visceral disease, and the rectal temperature was 98.2° F. Within the next week some diminution of the induration was noticed, and improvement was steady from that period. As the hardness cleared up no pitting was obtained on pressure, and instead of decreasing evenly in all directions isolated islets of induration remained upon the arms and elsewhere. Within four months recovery was complete. The treatment employed was inunction of cod-liver oil, and for four weeks inunction of blue ointment. The nature of the case was discussed and reasons were given for regarding it as an example of sclerema rather than of oedema neonatorum. It was shown by reference to certain recorded cases of sclerema that the case was one of a well-defined group, the members of which exhibited close resemblances in their clinical features, and all ended in recovery. It was suggested that possibly such cases might turn out to constitute a third category, distinct both from the typical fatal sclerema and also from oedema neonatorum. Although the improvement was perhaps more rapid during

the period when mercurial inunction was employed, it had already commenced before the blue ointment was prescribed, and continued without interruption after it was stopped.—Dr. KESER said that it was not often that cases of this kind were seen to recover. He had a severe attack himself, and his brother died from it; his own recovery was attributed to warmth and diet. He had seen some incomplete and abortive cases of this disease. The first was a child born six weeks before term; it was weak, thin, had digestive disturbance, and suffered from bronchitis when a fortnight old. At the age of seven weeks the skin of the penis was noticed to be hard, and in two days the hardness had spread to the lower abdomen. It improved; then relapsed, and then ultimately the disease disappeared, the child dying afterwards from broncho-pneumonia. In the second case the child was born at term, but had been badly fed. At the age of one month induration was found in the left gluteal region, and it extended to the thigh and lumbar regions; the temperature was subnormal. The child was kept warm and on a full diet, and it recovered. In the third case the child, aged one month, developed a patch on the left cheek and ear, but these disappeared without any treatment. In Dr. BARRS' case the skin was red, and the parts involved were those touched by the napkin. The first case of which he had found a description occurred in 1718 at Ulm and was attributed to a maternal impression, the mother while pregnant having gone to a church and looked attentively at some statues.—Dr. COLCOTT FOX said that the disease was rare and was less common in England than it used to be. In certain typical cases of sclerema and of œdema respectively they could be distinguished from one another, but in many instances it was difficult to make a distinction. The first case he had seen was one of isolated bosses over the deltoid. Sclerema was said usually to begin over the lower extremities, to spread upwards, and to involve the face. In œdema the dependent parts of the body were particularly involved—the back, the buttocks, the back of the arms and the calves, but not so often the face.—Dr. COLMAN said that in most of the published cases of this affection the descriptions were indefinite and confused. In sclerema, which was usually fatal, there was an increase of fibrous tissue in the skin, whereas in œdema, which was usually recovered from, there was a physical alteration in the subcutaneous fatty or areolar tissue. It should be remembered that the skin of a new-born child was very different from that of a grown child or of an adult, and œdema would not pit in new-born children as it would in an adult. Most cases of sclerema had been put down to syphilis, but the fact that they had recovered under anti-syphilitic treatment was not sufficient evidence of syphilis. In two cases of œdema neonatorum he had found post mortem very evident visceral syphilis.—Dr. GARROD, in reply, said that in the case he had related the temperature had been depressed a degree or two; there was a nodule in the parotid region, but not distinctly on the face. The trouble commenced in the buttocks and spread upwards. The mercurial treatment might have hastened the recovery, but it did not initiate it.

BRITISH GYNÆCOLOGICAL SOCIETY.

Adjourned Discussion on the Dangers of Morphia in Gynaecological Practice.—Exhibition of Specimens.

A MEETING of this society was held on April 11th, Dr. CLEMENT GODSON, President, being in the chair.

Dr. LEITH NAPIER, continuing the discussion on Dr. Macnaughton Jones' paper,¹ said that too much stress had been laid in the paper on the influence of temperament. He concurred with the author's adoption of Zambaco's classification of morphia patients: (1) those suffering from chronic painful disease who had daily recourse to morphia; (2) those who had been cured of such affections but continued to use the drug; and (3) those who indulged in morphia for the mere pleasure it afforded. He called attention to some symptoms of the morphia habit which had been overlooked in the paper, such as sickness severe enough to contra-indicate the drug even when pain was great, various cutaneous rashes, and general pruritus. Women were more susceptible to morphia than men were, reacting readily to its exciting as well as to its sedative action. He held strongly that whilst morphia should be given for relief of pain, less potent drugs should replace it

in insomnia and neuroses; for instance, the bromides, lactophenin, chloralimid, erythrina, sulphonal, and paraldehyde.

Dr. C. A. MERCIER said that not everyone who took morphia habitually was a morphinomaniac. Thus De Quincey indulged in an opium debauch at frequent intervals from 1804 to 1812; at no time during these eight years was he a slave to the drug. In 1813 a severe and painful illness led him to the daily use of laudanum, and it was only then that it obtained a complete mastery over him. He describes himself in 1816 as sitting down every night with a quart decanter of laudanum at his elbow, and he drank it without measure and without stint. The absolute dependence upon morphia and not the mere indulgence in it, however frequent or prolonged, constituted morphinomania. De Quincey was able to abandon the habit, and did so at the cost of intense suffering, without, as far as they knew, any external assistance or advice. But he never used the hypodermic syringe. It was a matter for consideration whether the tyranny of morphia administered by the syringe was not far more dominating than when it was taken by the mouth. Dr. Macnaughton Jones had pointed out that attention was first called to the prevalence of the morphia habit in 1864, and it was about that time that the syringe came into fashion. It was a remarkable fact that a successful means of breaking morphia-takers of their habit was based upon the much greater facility with which it could be abandoned when taken by the mouth. A large proportion of the daily ration of morphia could be cut off without great distress: the crux was reached when the daily quantity was reduced to one or two grains. At this stage the syringe should be abandoned, and double or treble the quantity given by the mouth. It was then possible to rapidly diminish and at last to altogether abolish the dose without occasioning any very severe distress to the patient. The conclusions that he ventured to put before the society were that the syringe should be reserved for cases of great agony requiring immediate relief; that a long course of opium, when needed, should be given in other ways; and lastly, that it was almost criminal to entrust a patient with a syringe for the self-administration of morphia.

Mr. J. F. WOODS (Hoxton House Asylum) said that he had met with six cases of the morphia habit. One was that of a medical man admitted under certificate and suffering from delusions. He had been taking twenty grains daily, hypodermically. After an attempt at suicide he was allowed his syringe, with an attenuated solution of morphia, so that instead of two grains (as he thought) he was taking one-twentieth of a grain for a dose. He improved rapidly and left in two months. After an interval he had a relapse and was again cured; some time afterwards he committed suicide by taking an overdose of chloroform. Another case was that of a woman aged forty-nine years who had taken morphia for fourteen years, having begun it under the direction of a medical man for uterine pain. On admission she gave up four syringes and two bottles of morphia. On stopping the drug she suffered from great restlessness, but he was able to cure her by hypnotic suggestion. She made rapid progress and gained two stones in weight. He heard from her last week, and she was then quite well.

Dr. T. OUTTERSON WOOD thought that it was not in asylum practice that the majority of cases were met with—it was rather among borderland neurotics; and that when their condition passed into certifiable disease recovery was rare.

Mr. W. D. SPANTON (Hanley) hoped that gynæcologists would not be held responsible for all the evils of morphia, for among men the habit was relatively more common than was usually supposed. Under no circumstances ought a syringe to be placed in the hands of a patient.

Dr. FITZGERALD (Folkestone) said that he would confine his remarks to the use of morphia in painful and hopeless malignant disease. It was the duty of every conscientious physician not only to alleviate pain where a cure was impossible, but also to ensure a painless death when the end came.

Dr. MORTON, while admitting the great value of morphia in such cases as cancer, thought that in dysmenorrhœa and allied conditions it was only very rarely needed; there was here a large scope for the recent antipyretic and analgesic drugs.

Dr. MACNAUGHTON JONES, in reply, emphasised the fact that his paper dealt only with the influence of temperament on the susceptibility to morphia intoxication. He had proved the contagiousness of the habit in some cases. Sterility was one of the acknowledged results of morphinism, and he

¹ THE LANCET, March 23rd, 1895.

gave an instance in which conception occurred after the habit was cured. Reviewing the treatment of the morphia craving he touched on the various plans: by abrupt stoppage (Lewinstein); more gradual lessening (Erlenmeyer); and the middle course of ceasing to give the morphia after a gradual decrease of the quantity had been carried over a period of from eight to twelve days. The last plan, combined with the use of various hypnotics, had given him the best results; treatment by alcohol, chloral, opium itself, the substitution of water, nitro-glycerine, &c., all failed. But it was no part of his object to discuss treatment. His main proposition was that in women suffering from subjective pain and pain arising out of functional disorders of the uterus and ovaries the risk of using morphia subcutaneously was great.

Mr. W. D. SPANTON showed the following specimens:

(1) very large Cyst with Cystic Ovary removed from a married woman aged thirty years; (2) Renal Calculus of Phosphate of Calcium weighing 980 grains removed by Right Nephrolithotomy from a married woman aged forty-three years; and (3) an Imperfectly Developed Ovary with large Graafian Follicle removed from a married woman aged thirty years. In all these cases recovery followed.

Dr. LEITH NAPIER showed an Obstetric Forceps with a New Lock, the invention of Dr. Bourke.

KIDDERMINSTER MEDICAL SOCIETY.

Removal of Testes for Enlarged Prostate, with notes of two Surgical Cases.—Scarlet Fever.—Exhibition of Cases.

A MEETING of this society was held on April 5th, Mr. D. CORBET, President, being in the chair.

Mr. J. L. STRETTON gave a further report on the Removal of Testes for Enlarged Prostate in a patient whose case was read at the last meeting. When discharged from the infirmary on Feb. 20th he was able to walk about; his urine was clear and was passed naturally. A few days later he again became delirious and much exhausted, and although he recovered temporarily he gradually lapsed into the same condition, and ultimately died on March 16th. At a necropsy on the following day the body was found to be emaciated, the bladder distended with urine, its coats much thickened, and its internal surface very irregular, large muscular bands traversing it in all directions. The prostate was about the size of a bantam's egg and exhibited no signs of tubercle. That the operation gave the patient relief there is no doubt; it materially reduced the size of the prostate and restored the power of micturition. Had it been undertaken at an earlier date, before his constitution was so much impaired, it would probably have prolonged his life. A woman aged seventy years was admitted on March 5th with Strangulated Umbilical Hernia. She had been ruptured six or seven years, but had always been able to return it. It had been strangulated about thirty-six hours, and she had had faecal vomiting, her general condition being unsatisfactory. An incision was made over the tumour, and the bowel, which was dark and congested, was returned after the ring had been nicked, the edges were freshened and brought together with deep sutures, and the skin wound closed. The operation from the commencement of the anaesthetic occupied less than half an hour. She passed flatus on the second day, the bowels acted on the fourth, and the stitches were removed on the sixth; her general condition had improved and she appeared to be going on quite well. Two or three days later she passed blood in her urine and became restless. She could not tolerate the catheter, and her symptoms became so grave that a further operation was out of the question. She died on April 1st. At a necropsy twenty-four hours after death there was complete closure of the aperture at the site of operation and no signs of peritonitis. The bladder was thickened and contained two phosphatic concretions; there were two cavities in the right kidney containing pus, and a small ovarian cyst on the left side. Mr. J. L. Stretton urged the importance of simplifying such operations to ensure their rapid performance, especially as there was the possibility of other organs being involved, as in this case, without presenting any symptoms. A man aged twenty-two was bitten seven or eight years ago by a horse about the upper part of the abdomen and two cicatrices were left. Two years ago the present condition commenced and had been gradually increasing. He was a well-developed healthy looking man. Over the lower part of the right chest in front was a large mass of new growth which was irregular in outline

and had a mottled purple and red colour; it measured at the base 4 in. across and 2½ in. from above downwards. At the lower end of the sternum was a similar mass 1½ by 1¼ in. They were freely movable on the deeper tissues and had a soft elastic feel at places. Both tumours were removed by one incision, leaving a large surface which could not be covered by skin. He made an uninterrupted recovery. Skin grafts were planted from time to time, and the whole had healed in three months. Microscopical examination showed round-celled sarcoma.

Dr. EVANS showed a case of extreme Enlargement of the Thigh Bone following Fracture.

Dr. P. E. DAVIES brought forward a female child aged eleven years suffering from Congenital Syphilis with well-marked Ulceration of the Soft Palate, which he considered a rare condition.

The PRESIDENT read a paper on Scarlet Fever.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Impacted Gall stone.—On certain Abnormalities of Convolution and Structure in the Brains of the Insane.—Exhibition of Specimens.

A MEETING of this society was held on April 5th, Mr. A. W. Mayo Robson, Senior Vice-President, being in the chair.

Dr. CHADWICK reported a case of Impacted Gall-stone (Jaundice, six years' duration), where a solitary attack of biliary colic (January, 1889) was followed by jaundice, which persisted till death six years later (December, 1894). The case when seen in 1892 was regarded as one of malignant disease, there being hepatic enlargement, tenderness on pressure, and much ascites, without any obvious splenic enlargement. When seen in 1894 the abdomen was retracted, there was no ascites, the spleen was enormously congested, and there was copious hæmatemesis, followed by death in a few days. An impacted gall-stone was found post mortem. The case was interesting on account of its long duration. Xanthelasma was present in 1892, but was not demonstrable in 1894. No indication of any malignant change was apparent anywhere.—The case was discussed by Mr. Mayo Robson, Dr. Eddison, Dr. Major, and Dr. Barrs.—Dr. Chadwick replied.

Dr. W. LLOYD ANDRIEZEN (West Riding Asylum) gave a demonstration on certain Abnormalities of Convolution and Structure in the Brains of the Insane, illustrated with several specimens of crania and of brains in epileptic idiocy and imbecility, including also imbecile brains in which the patients were not subject to epilepsy. Dividing the insanities into two great classes, at one extreme of which hereditary vice of organisation prevailed, it was shown that the above pathological specimens came within the above category. The insanities at the other end of the scale include such as mania, melancholia, stupor, the toxic insanities (like alcoholic), &c., with the last of which he had fully dealt elsewhere. These latter presented no striking anomalies of conformation or convulsion, and many of them might be conveniently included under the term "acquired" insanities. After showing that a large intermediate group of insanities existed between these two extremes of the scale—a group which he would with Marel, Magnan, Krafft-Ebing, and others designate as a "degenerative" group, it was shown how these degenerates frequently exhibited not only certain psychical characters or stigmata, which stamped them as such, but also physical characteristics of physiognomy and of brain and bodily conformation (somatic stigmata). Reserving fuller details on these for a separate communication, it was shown that in epileptic idiocy and imbecility the condition of cranial asymmetry was a striking and preponderating feature; and this the speaker proceeded to correlate with anomalies of brain development in these subjects. Case 1: An epileptic imbecile, fits since the age of four, right arm paralysed (with sclerosis and atrophy of the left Rolandic area in the brain) but liable to some active (tonic and clonic) movement when a fit occurred. The condition was one mainly of microgyria with atrophy and sclerosis of convolutions on the left side generally, and with these a parallel atrophy of the right lobe of the cerebellum was also shown to exist. Case 2: An epileptic idiot, fits since infancy.

1 On Some of the Newer Aspects of the Pathology of Insanity. Brain, 1894.

general. The left hemisphere was of fair size and development; the right hemisphere was atrophied and sclerosed very beautifully and uniformly over the supra-marginal, occipito-angular, and temporo-sphenoidal regions (externally and mesially) over an area corresponding very accurately to the distribution of the posterior cerebral artery. The anterior and middle cerebral area had practically not suffered. The significance of this in connexion with syphilitic and alcoholic disease in the parents was shown, and further examples given of such diseases in the parents affecting the brain development of the child. Case 3: An epileptic idiot, microcephalic, showed disseminated microgyria in small territories (upper frontal, parieto-angular, &c.), unevenly scattered through both hemispheres. Other cases of epileptic idiocy were described and by the aid of photographs their pathogenesis was discussed, the conclusion being arrived at that a sclerotic overgrowth of the neuroglia fibre cells (diffuse or focal, and in the latter case often corresponding to a particular vascular territory) with a corresponding slow irritation, destruction, and finally atrophy of the nerve cells and fibres in the same area underlay the phenomena of epileptic idiocy and imbecility. Further details were given of several epileptic imbecile brains (about fifteen) examined microscopically, and one of a case of "focal epilepsy" in which the area of brain cortex excised in a surgical operation by Mr. Victor Horsley, was also investigated by the lecturer. Each and all of these concurred in showing the above type of lesion (diffuse, with small focal destructions of nerve tissue), all pointing to the same pathogenic basis in epileptic idiocy and imbecility, and in focal epilepsy. (Full details would be published later in a memoir in course of preparation.) In the brains of simple—i.e. non-epileptic—imbeciles and idiots such lesions as the above were absent, and the convoluted forms might be, and often were, plump and well formed, though inclined to simplicity of arrangement. These were to be looked upon as general arrests of development primarily. Amongst others was shown the case of a congenital idiot (non-epileptic), speechless, dirty and degraded in habits, finally dying from phthisis at an adult age (thirty), which realised such a plumpness and yet simplicity of general brain convolution, and in which no condition like microgyria was present. (All cases of hæmorrhages, parencephaly, traumatism, &c. involving destructions of brain tissue *ab extra* were excluded from the present research to prevent complications in the study.) Further remarks were also made on pachymeningitis hæmorrhagica, and on the hardness and structure of the cranial bones in the insane.

Dr. ADOLPH BRONNER (Bradford) showed a case of Caries of the Attic in which Stacke's operation had been performed. There was a history of discharge from the ear off and on for eight years, with occasional attacks of severe pain. Perforation of Shrapnell's membrane was found and treated for several months. The ossicles were then removed, and extensive disease of the bone found. The external ear was drawn forward, the cutaneous part of the external meatus cut through and pulled out, and the diseased bone removed by chisel and sharp spoon. The ear was replaced. After five weeks no rough bone could be felt. The wound behind the ear was kept open by lead wire.—Dr. Bronner also showed a case in which Trichiasis of the Upper Lids had been treated by transplantation of mucous membrane of the lip. An incision was made along the edge of the lid below the cilia parallel with the skin and a strip of mucous membrane of the lip inserted into the incision and attached with catgut sutures. In the other eye a piece of the skin of the upper lid was transplanted. The mucous membrane seemed to heal quicker than the skin.

Dr. HELLIER: Large Subperitoneal Myoma removed from Uterus.

Mr. LITTLEWOOD: (1) Vermiform Appendix removed from a case of Recurrent Appendicitis; (2) Tumour of the Lower Jaw weighing 30 oz. (twelve years' growth).

LIVERPOOL MEDICAL INSTITUTION.

Lung Cavity Incised and Drained.—Two cases of Cleft Palate to show the Natural Voice some years after operation.—*Rhinoliths.*—Treatment of Delirium Tremens.—Modern Miracles of Healing.

A MEETING of this society was held on April 18th, the President, Mr. CHAUNCEY PUZEY, being in the chair.

It was proposed by Mr. LOWMESE, seconded by Mr. BARK,

and carried, "That a subcommittee be formed to consider the recommendations of the Select Committee of the House of Commons on Death Certification."

Mr. CLEGG read notes of a case of Cavity of the Lung which he had incised and drained, and also referred to similar cases which had been under his care but which he had not operated upon.

Mr. CLEGG also showed two children about eight years of age on whom he had operated for Cleft Palate some four years before; in both instances the voice had been very materially improved.—Messrs. Rawdon, Harrison, and Murray made remarks.

Mr. BARK read a note on Rhinoliths and related the case of a woman aged twenty-six, seen in November, 1893. She complained of blockage of the right nostril, purulent discharge, frontal headache, and epiphora. These symptoms had been coming on for three years. After cocaineising the right nostril a jelly-like mass could be seen on the floor of the nose, with white calcareous points shining through it. The mass was immovable, being firmly embedded in granulations. Under chloroform considerable force was required to extract the stone. The granulations were subsequently removed by the cold snare and galvanocautery. The patient made a good recovery. Mr. BARK said that nasal calculus was a sufficiently rare condition to make it advisable to report this case. He entered at some length into the causes for the formation of these stones and the way in which they could be best detected.—Dr. PERMEYAN made some remarks on this paper.

Mr. DAMER HARRISSON read a note on the Treatment of Delirium Tremens. He referred especially to the violent mania which sometimes occurred in robust drunkards after injury or otherwise. He advocated a return to the plan introduced by Graves of first depressing the patient by antimonial wine and then giving narcotics, but he preferred chloral rather than opium. Dr. Macfie Campbell, Dr. Rawdon, Mr. Nicholson, Dr. Carter, Dr. J. Wigglesworth, and the President discussed Mr. Harrison's paper.

Dr. IMLACH read a paper on Modern Miracles of Healing. He brought forward five women, all of them examples of the Holywell cure. One of them had been in the Royal Infirmary upon two occasions, each time for a month, with swelled right leg; she was told that there was plugging of the lymphatics, and upon the board at the head of her bed the disease was entered as elephantiasis. The swelling began in the ankle and rose above the knee. Rest, massage, bandaging, and other treatment having proved useless her parents took her to Holywell last autumn; after bathing in the water the swelling began to disappear, and was gone in a few days. A photograph of the swollen leg was shown to the meeting. Another cure which had been under Dr. Oliver of Newcastle-upon-Tyne, and had been already described in THE LANCET,¹ was carefully examined by those present at the meeting. There were also three examples of chronic rheumatism. Previously to their visit to Holywell they had been for many years martyrs to rheumatism and all medical treatment failed to relieve them. They had all been cured by a visit to the well last autumn and had passed through the severe winter without an ache or pain. Dr. Imlach thought that to question miracle was mere foolishness, and to question the cure was impossible. What remained was to determine scientifically *what* was cured, and this was no easy matter. He referred to the cures at Lourdes and expressed a hope that medical men would assist in investigating the actual worth of the Holywell recoveries. An interesting discussion followed the reading of the paper, in which the President, Dr. Sumner, Dr. Glynn, and Mr. Head took part.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

The Treatment of Severe Hæmorrhage by the Infusion of Normal Saline Solution.—Exhibition of Specimens.

A MEETING of this Section was held on March 29th, Dr. R. D. PUREFOY, the President, being in the chair.

Dr. GLENN, having expressed his indebtedness to Dr. Smyly, briefly described the five methods of using Normal Saline Solution in Severe Hæmorrhage—namely (1) Munchmeyer's injection into the connective tissues; (2) Ponfick's

¹ THE LANCET, March 16th, 1895.

intra-peritoneal infusion; (3) rectal injections; (4) intra-venous infusion; and (5) intra-arterial infusion, either centripetal or centrifugal. Munchmeyer's method he considered too slow, but recognised the value of the accompanying massage, especially when applied to the abdominal walls, as the large reserve of blood held by the abdominal veins is thus encouraged to flow towards the heart. Intra-peritoneal infusion was employed in several laparotomies, three or four pints of normal saline solution being left in the peritoneal cavity with markedly good results; the patients recovered with exceedingly slight shock considering their loss of blood, the only special feature being an intense thirst which persisted for twenty-four hours. Rectal injections can be employed at the will of the operator at any time during an operation. These methods, though useful, have in no degree the value of the remaining two—intravenous and intra-arterial infusion—at least so far as the immediate treatment of profuse hæmorrhage is concerned. Having glanced at transfusion of blood and its difficulties when employed in private practice, he quoted Jennings's conclusion: "We know that blood excels saline fluid on nutritive grounds, but the dynamic effect of the operation being that generally required to restore suspended animation, saline fluid will usually be found sufficient." Sir Spencer Wells first suggested the infusion of normal saline solution in England, founded on experiments during the cholera epidemic of 1848. Lande and Bischoff in Germany—Jennings, Arbuthnot Lane, and Herbert Spencer in England—were its pioneers. The apparatus used in Dr. Glenn's cases was one made by Collin of Paris, and was found admirable, being simple, easy to work and to keep aseptic. The rate of injection was recommended to be three ounces per minute as a maximum, on the authority of Panum. "Slowly and regularly" is generally the most important thing in the operation. The temperature will depend on the apparatus used, as allowance must be made for cooling in passing through. The quantity depends on individual requirements; certainly we should go on until a slowing of the pulse with an increase of volume is noticeable. Worm-Müller has shown that an increase of blood to the extent of four-fifths of the normal amount can be borne without injury to the individual into whom it is injected. The injection of large quantities has been followed by more favourable results than were obtained when smaller amounts were employed. Horrocks used two to six pints, Herbert Spencer one and a half to two pints, Bernard Pitts two to eight or ten pints, while in Dr. Glenn's cases eight pints were the maximum; the addition of alcohol is of no benefit. The advantages of arterial infusion in fat anæmic patients were pointed out, the stimulation of the medulla oblongata by the centripetal method being emphasised. The absolute importance of all bleeding points being secured was dwelt upon, and a warning was given against over-hastily using it in post-partum hæmorrhage. Dr. Glenn then read notes of seven cases of the use of this method in gynecological practice, in three of which the patient recovered.—Dr. TWEEDY said that he had seen most of the cases infused, and had himself infused eight other cases. He agreed with Dr. Glenn as to the enormous improvement that took place in the patient's pulse and appearance, but considered it to be very transitory. He believed that the saline infusion acted as a stimulant to the heart, and that it had saved several lives by warding off impending syncope. It, however, flowed out of the vessels nearly as quick as it went in. There were free urination and perspiration. In one case fluid poured from a drainage-tube in the abdomen ten minutes after infusion. A patient very rarely dies from absolute want of blood; it is shock that kills her. Nearly as many blood corpuscles have been found in a woman who died from hæmorrhage as in a chlorotic girl. The patient dies because the heart is too sluggish, not because it has nothing to contract on. He had used a simpler instrument than that shown by Dr. Glenn. If he was not absolutely sure of his asepsis he would not ligature the vein, but would only put on a compress and bandage, following Dr. Stoker's advice.—Dr. A. SMITH had seen several cases infused with saline solution, but only with temporary improvement. He had done it two or three times himself. In one case the ligature had slipped from an ovarian pedicle. The patient was very collapsed. He reapplied the ligature and put saline solution into the abdomen, and found slight improvement, which died away very soon. He then put the patient in an exaggerated Trendelenburg's position and got great improvement. The patient recovered. He looked on the case as one

of auto-infusion. He had another very similar case in which Trendelenburg's position seemed to do a great deal of good. He was not a strong advocate for transfusion. He thought the principal question was, "When to transfuse?"—Mr. S. M. THOMPSON said that he had seen transfusion used in 1868 for cholera. There was great temporary improvement, but the patients never recovered.—Dr. BATE mentioned that in Berlin six months ago he had seen a case of miscarriage in which two or three pints of saline solution were put into the breast, distending it enormously. He examined the breast two or three days afterwards and found that it had quite regained its normal size. The patient derived great benefit from the injection and recovered.—Dr. SMYLY said that he remembered Dr. Beatty reading a paper on a case in which Dr. Robert MacDonnell had infused defibrinated blood; the woman made a good recovery. When assistant in the Rotunda he saw transfusion performed, followed by death from pulmonary embolism. He had no hesitation in saying that the present was a very great improvement on the old method. He had not seen any evil results follow from the salt-and-water method, and patients had recovered whose condition appeared to be hopeless. In answer to Dr. Smith's question of "When to transfuse?" he would say, "When in doubt, operate." Salt-and-water was the best stimulant that could be given. He had had one patient transfused simply for shock and not for loss of blood. He thought that the credit of reintroducing this method in Dublin was altogether due to Dr. Glenn.—Mr. LANE agreed with Dr. Tweedy and Dr. Smith in the nature of the temporary effect produced in the majority of cases of transfusion. He had seen Dr. Macan use an instrument very similar to Dr. Tweedy's, but provided with a graduated glass jar, which was an improvement. If the effect of the saline infusion was only to stimulate a sluggish heart the question would have to be considered whether alcohol or some other stimulant would not do as well.—The PRESIDENT said that the first successful case of transfusion occurred when he was at the Rotunda. It was done by Dr. R. MacDonnell, and one of the students furnished the necessary blood, eight ounces, which was defibrinated. A much smaller quantity was used than is used now. It was when a secondary collapse had set in, several hours after delivery, that the transfusion was done.—Dr. GLENN, replying, said that as regards the quantity infused he thought the present results, in which pints instead of ounces were used, were more favourable. Other stimulants, as alcohol and ether, were always used in conjunction with infusion of saline solution. He considered the instrument used by himself to be superior to Dr. Tweedy's. The latter would require nine feet of tubing if the infusion was into an artery, but in his he could get the necessary pressure with the syringe. In Dr. Smith's cases the elevation of the legs could not have been the cause of the patients recovering, considering the very small amount of blood in the legs. The advantage of Trendelenburg's position was that the abdomen was raised and pressure applied to it. The manner of infusion described by Dr. Bate was merely Munchmeyer's method into the connective tissue. It was an unsatisfactory method, as it was too slow. Infusion was very unsuccessful in cholera.

Dr. SMYLY exhibited specimens of Uterine Myoma, Epithelioma of the Cervix, Double Pyosalpinx, Interstitial Salpingitis, and Ovarian Cystoma.

Dr. F. W. KIDD exhibited a Submucous Fibroid removed from the Uterus by enucleation.

SECTION OF PATHOLOGY.

A Rare Tumour.—Fibro-myoma of Tongue.—Dentigerous Tumour of the Neck.—Orbital Tumour.—Malignant Disease of the Ear.

A meeting of this Section was held on April 5th, Dr. J. A. SCOTT, the President, being in the chair.

Dr. PARSONS read a paper on the Microscopical Section of a Rare Tumour.—Professor M'WEENEY thought that the growth was justly called a cylindroma, but that it did not belong to that class which occurred from hyaline degeneration of the bloodvessels, because the hyaline strands were very closely placed together, and there were very few cells. He had himself seen only one case of cylindroma. It occurred in the hard palate and was adherent to the bone. It was removed six times, recurring each time.—Dr. PARSONS agreed with Professor M'Weeny that the tumour must first have been very vascular. It was three years since the tumour was removed, and he had not seen the patient since.

Professor M'WEENY showed a Fibro-myxoma, an encapsuled, translucent, yellowish tumour about the size of the kernel of a hazel-nut, removed from the tongue of a man aged twenty-three years. There was no history of syphilis, either congenital or acquired. Histologically examined after fixation in Foh's reagent, the tumour proved to be a fibroma, with here and there so much structureless or faintly fibrillated ground substance as to justify the name myxoma.

Professor M'WEENY also showed a Congenital Dentigerous Tumour removed from the left side of the Neck of a woman aged twenty-three years. The tumour, which was small at the time of birth, had increased steadily until, at the time of operation, it had attained the dimensions of a good-sized orange. It was subcutaneous, with deep attachments, and sprang from the level of the hyoid bone, to which it was adherent by a sort of process. To the naked eye it seemed made up of a dense fibroid stroma, in which were embedded numbers of cysts, averaging the size of a pea, filled with mucoid material. The trabeculae between these cysts were dense and thick, and contained many bars and nodules of cartilage, as well as several immature-looking teeth. In the growth were also calcified corpora amylacea and other structures of a doubtful nature.

Mr. ARTHUR BENSON and Mr. GRAVES communicated the notes of a case of Orbital Alveolar Sarcoma in a man aged fifty-five years. The growth seemed to start from the region of the lacrymal sac and was about the size of a small hen's egg, hard and lobulated. It protruded forwards in the region of the left lacrymal sac, and over it the skin was tense, thin, and adherent to the apex. The eye was pushed forwards and outwards to a considerable extent. The fundus of the eye was normal, and the motions of the globe were but little impaired. After removal of the growth the eye returned almost to its normal position when the wound healed.

Mr. STORY described a fatal case of Malignant Disease of the Middle Ear, the first he had observed in eighteen years, during which period over 12 000 aural cases had come under his observation at St. Mark's Hospital. The patient was a man about thirty years of age from whose middle ear a polypus was removed in September, 1894. The polypus returned again and again after removal, necrosis of part of the temporal bone showed itself, and the patient finally died from exhaustion within six months after the removal of the first polypus.—Professor SCOTT showed microscopic sections of the tumour in the ear and of a secondary growth in the neck, both of which he regarded as sarcomatous.—Dr. BENSON said he saw the case before the present diagnosis was arrived at, and the idea of malignant growth had never occurred to him. At that time it looked very like a severe case of mastoid implication as a sequence of middle-ear disease.—Mr. STORY, replying, said that before the microscopical examination was made he thought it was probably an epithelial growth. The patient died, not from perforation of the malignant growth into the cranial cavity, but from exhaustion, with difficulty in deglutition, which came on simultaneously with loss of speech.

Reviews and Notices of Books.

The Evolution of the Diseases of Women. By W. BALLS-HEADLEY, M.A., M.D. Cantab., F.R.C.P. Lond., Lecturer on Midwifery and the Diseases of Women at the University of Melbourne, &c. London: Smith, Elder, and Co. 1894.

THIS is in many ways a somewhat exceptional and bewildering book, if we are to regard it, as we suppose we must, as belonging to medical literature. The author is a teacher of midwifery and of the diseases peculiar to women at the University of Melbourne—that is to say, of two subjects essentially practical—and it might have been expected that a work by him on the Diseases of Women would have dealt with this subject practically, in a manner that would have afforded help to the practitioner who has to recognise these diseases and to relieve them as far as the present state of our knowledge permits. On the other hand, if the author desired to write a work on political economy, or on social questions, and more especially on the relation between the sexes, it was obviously unnecessary to attempt to combine with it a book

on the Diseases of Women. Such familiar works as "Esther Waters" and "The Woman Who Did" are examples to the point. It seems better to leave questions of social philosophy to the novelist rather than to combine them with the teaching of matters strictly medical. In the preface we read: "Evolution is the mode of progress of the world. Nothing is, that is not the gradual development of events. Progress for good or evil is the sequence of Nature. The destruction of a nation is the culmination of the effects of destructive agents. Death, except when solely from accident [is an accident 'the gradual development of events'?] or effluxion of time, is but the manifestation of undue waste of vital action, the neglect of an evident causation. It is an evolving destruction. In woman this is peculiarly apparent. Her life, as woman, is a wonderful vicissitude. Her destruction comprehensible, prognosticable, remediable." Chapter I. deals with the relation between the sexes. On page 2 we find a paragraph on dolls, which though, no doubt, true enough, and in some respects interesting, is scarcely gynaecology. We take exception, however, to the statement that boys do not play with dolls. Up to a certain age they certainly not unfrequently appear to enjoy playing with them as much as little girls do. The late Dr. Matthews Duncan began one of his clinical lectures with the words, "Who in this world can say what anyone means by endometritis?" This is how Dr. Balls-Headley defines it: "Endometritis is an evolutionary inflammation of the membrane lining the uterus, and though frequently affecting this structure throughout the organ may be of the cervix only, or of the body, the condition differing in accordance with the variation in the anatomy of these parts and the manner of the causation. This is the central essential disease in evolutionary pathology, is exceedingly common, and is worthy of the utmost consideration." In giving the symptoms of cervicitis the author says: "There is sterility when the canal is blocked by the cohesive mucous plug." Has anyone ever seen an os uteri that was not occupied by a cohesive mucous plug? We think not; and we doubt if anyone has ever seen the os uteri blocked by it. As regards the prognosis of this condition he says: "The prognosis is that the disease will be continuous with evolutionary progress if not surgically treated, and sterility, except in the mildest cases in which the disease is not really confirmed, is certain." It is difficult to understand what is meant by the first part of this, but the latter part—that sterility will be certain in cases where the cervical canal is occupied by adhesive mucus—appears to us quite at variance with the general experience. Indeed, the use of the word "blocked" is an index to the kind of way in which the author combines statements of fact with statements involving a theory that may or may not be true. To say that there is always mucus present in the cervical canal normally is a statement of fact; to say that the canal is "blocked" by such mucus involves the view that it exercises a detrimental influence in some way or other—a view that is, in the opinion of the best authorities here, altogether incorrect. An example of the author's system of reasoning is afforded by the following quotation, in which it will be seen that endometritis is ascribed to overdress: "The evil of overdress is apparent; but it is due to the deficiency of marriage and the misapplied competition of attraction. At first the young girl, with inherent instinct, properly expects that the attraction of her sex, as in the case of the birds she sees, and of all creatures, will be sufficient to insure her a mate. No mate offers. She attempts to increase her attraction, and spends all her money on adornment. Still she is unwed. Time advances; she buys bonnets, dresses, bangles, white and tan shoes; and, if comparatively poor, is perhaps deficient in underclothing; she is dressed far beyond her station, and therefore that of her probable husband, frightening such men from her side.

..... She finally grows thin and atrophies—a wasted woman—and in future, should she be dependent on her own exertions, as are so many women in this age, a drudge to sustain her body in food, unselected, and hopeless : and evolutionary disease, such as endometritis, may ensue." And again, in the chapter on the Granular Os—by which, we suppose, is meant the slight erosion round the os uteri, so commonly seen that, in its slighter degrees at all events, men of moderate views have come to regard it as scarcely pathological—"endometritis occurs by the chronic congestion of unsatisfied passion with exacerbations." The author is of opinion that "no woman with granular os is free to the last days of her life from the risk of super-development of malignancy on the granulations." There is no sort of scientific evidence that there is a causal relation between slight erosions of the cervix and malignant disease, and the sentence we have quoted is only true in so far as it implies that no woman at all is free from the risk of malignant disease. The book is full of similar instances of loose reasoning. So far as we are able to follow the author it appears that he ascribes nearly all the ills to which female flesh is heir to unsatisfied sexual passion, aggravated by tight-lacing, forgetting how frequently in actual practice we find that the patient enjoyed perfect health till she married, and how often all her troubles are found to date from then. We know, or if we do not it is not for want of frequent telling, that statistics may be made to prove pretty well anything; but their power in that respect sinks into insignificance compared with a system of reasoning that assumes whatever is necessary for the argument—a system by which the author has satisfied himself that slight erosions lead to cancer, that endometritis is due to overdress, and that subinvolution of the uterus may be the cause of diabetes.

Cod-liver Oil and Chemistry. By F. PECKEL MÖLLER, Ph.D.
London : Peter Möller, 43, Snowhill, E.C. 1895.

THE curious title of this book would suggest that the author had conceived in his mind the utility perhaps of presenting to the reader a mental lubricant as it were before he is brought to grapple with the difficult subject of architectural chemistry, which is subsequently dealt with, and which occupies by far the greater portion of the volume. In that sense there seems to be no reason why we should not expect the issue of similar works with "castor oil and chemistry," "eucalyptus oil and chemistry," and so forth, for their titles. The fact is, the author is a consummate exponent of the theories of chemical constitution, and a good writer, while at the same time he possesses an interest in the cod-liver oil industry; he was not content, therefore, with giving a dissertation merely upon the chemistry of cod-liver oil, but also pure chemistry—a task which a perusal of the second portion of the work will show he was well qualified to undertake. Hence we welcome both contributions, despite the fact that we are inclined to suggest—so excellent is the treatment of both sections—that they might have been separated into two distinct volumes. To cod-liver oil the author devotes 111 pages, each lettered in Roman numerals after the manner of a preface. The account of Norway, its history, geography, its people, and their customs and habits, which involves a reference to the temperance problem, is full of interesting and entertaining reading, enlivened now and again as it is by a drollness and witticism of method which is occasionally employed even in the treatment of more occult things. Chapters on the various fisheries of which Lofoten is the centre follow, until in Chapter XLIII. the reader is presented with an excellent account of the manufacture of cod-liver oil, the modes of dealing with the fresh liver, and the various processes used for the extraction of the oil. Peter Möller's process (that of a relative, we presume, of the author), by which all the

disagreeable and detrimental qualities of the oil due to decomposed albumens were removed, was first introduced in 1853, and consisted in the treatment and extraction of the perfectly fresh liver by means of steam. The oil so obtained was a vast improvement, inasmuch as it was clear in colour, practically free from nauseating taste and smell, and consequently, as the author puts it, "a thing of delight from the consumer's point of view" and "an improvement of no small importance from the doctor's point of view." Next in order succeed a useful pharmaceutical chapter and an important chronological synopsis of chemical researches on cod-liver oil, together with new chemical researches contributed by P. M. Heyerdahl, than whom there is no greater authority on the composition and constitution of cod-liver oil. The author scouts the idea of the value of cod-liver oil being due to certain so-called "active constituents," as, for instance, certain alkaloidal bodies which have been isolated, so it is stated, from the liver, but which he says are not "normal constituents of pure cod-liver oil, inasmuch as valeric, cupric, and gadinic acids, gaduin, ammonia, trimethylamine, alkaloids, and such substances are partly decomposition products, formed in the hands of the analyst whilst conducting his operations, and partly products of bacterial activity after the oil has left the hepatic cells." His view, on the other hand, that cod-liver oil acts not by influencing the tissues, but by becoming part and parcel of them, or in other words by being simply food substances which in one way or another possess special advantages distinguishing them from other and ordinary foods, thus justifying their adoption as therapeutical agents, is, we think, the correct one. And, as he aptly puts it, "to attempt to find some such body in cod-liver oil is just as likely to be successful as would be an endeavour to find an active principle in, say, bread."

Part II. is a very remarkable production and treats of the law of atomic linking. We use the word "remarkable" because this section simply bristles with an excellent series of diagrams illustrative of the architecture of complex organic substances. The author offers an apology in the introductory remarks which we cannot accept, because, as we would assure him, it is wholly unnecessary. He refers to the "good old days" when "doctors calmly poured drugs down their patients' throats without knowing or much caring to know anything of their nature." "This simple method is now supposed to be rather out of date, and certainly the more intimate a physician's knowledge of his remedies the more likely is he to use them successfully." He then cites as an illustration the subject closest to his interest—cod-liver oil. Thus, owing to Heyerdahl's researches, already alluded to, it has been shown that "the views hitherto held regarding the nature of cod-liver oil are quite erroneous, and that we must now look upon that remedy in an entirely different light." Again, "without a certain intimacy with the views and theories of modern chemists and physicists it is impossible to understand or appreciate these and similar researches, and if anything in the following pages makes it easier for the busy practitioner to get at and grasp the facts of organic chemistry, then the writer's aim will have been fully accomplished." Could a writer possibly have any worthier aim in view? Anyone who cares at all for the advance of medicine, especially therapeutics and pharmacology, will not only thoroughly approve these observations, but will be grateful to Dr. Möller for the enormous labour he must have expended in his endeavour to show, in the most graphic and intelligible way, how a knowledge of the constitution of bodies generally must eventually place the administration of remedies on a more real and scientific basis, and so give the practitioner a stronger hold than ever over the mysteries and ravages of disease. We cordially commend this unique and clever work to our readers.

MAGAZINES FOR APRIL.

THE April number of the *Veterinary Journal and Annals of Comparative Pathology*, like the preceding numbers for the year, gives evidence of the change of editorship which took place in the early part of the year. Especially is this the case in the purely editorial department. The first article is an essay on Diseases Communicable from the Lower Animals to Man, read before the Edinburgh Medical Society by Mr. R. Peech, in which are considered some points in the history of the anthrax, glanders, and tubercle bacilli. A case of Pleuro-pneumonia of the Horse by Mr. F. B. Byrne is described, whilst the same author contributes a note on Labrum Poisoning, and indicates that an oleaginous aperient followed by demulcents and stimulants is perhaps the best treatment for this condition. Other papers, on Albuminuria in Cattle, by Edward H. Curbishley, M.R.C.V.S., and Simple Contusions and Some Sequelæ by Peter Moir, M.R.C.V.S., complete this portion of the journal. The editorial article is occupied with a discussion on Board of Agriculture appointments and examinerships and the advisability of keeping these confined to members of the veterinary profession. As, however, the question is discussed much more fully in the reports of the societies, where a good deal of feeling seems to have been engendered, the article may be simply a *résumé* of the feeling of these societies. A paper on Biliary Cirrhosis of the Liver in Cattle (Picton Cattle Disease) by Dr. Wyatt Johnston is reported together with a discussion in which Dr. Brydon and Dr. McKachran take part. An interesting note on the late Joseph Gamgee is also given. Reviews, which are not so numerous as usual, and reports of societies make up a sufficiently interesting number.

The *Veterinarian* for April, 1895, like its colleague, the *Veterinary Journal*, affords internal evidence, in addition to that contained on the cover, of a change of editorship. Both of the journals are now edited in Edinburgh. We have evidence of this in the number of the *Veterinarian* before us in the fact that the first two papers are both by Edinburgh authors, one entitled "Telephony," by Professor C. Ewart, on Lord Morton's well-authenticated experiments with breeding from the Arabian horse and the quagga. We are glad to see that Professor Ewart intends to repeat these experiments, and if they are successful they will be a severe blow to the theories of Weissmann and his school. Professor Mettam contributes an interesting paper on the Rudimentary Metacarpal and Metatarsal Bones of the Domestic Ruminants. Mr. J. A. W. Dollar has an interesting paper on Luxation of the Patella, in which he maintains that the patella is, as a rule, not truly displaced, but only retained at a certain point of its ordinary travel; where displacement does occur, however, it is always outwards, and must be accompanied by injury of the internal lateral ligament. Editorial notes and clinical cases, followed by abstractive notes and reviews, complete the number, from which it may be gathered that the *Veterinarian* under its new editorship is likely to be as vigorous as it has been during any period of its existence. An entirely new departure has been made in this number, as, by an arrangement with the editor of the *Veterinary Record*, which appears weekly, the reports of the various veterinary societies are reprinted, not in the body of the journal, but as a kind of supplement, so that although they do not form a part of the journal they may be kept as a permanent record of the proceedings of the different societies. This is an exceedingly good arrangement and one that might well be adopted in other monthly journals, the supplement being paged consecutively and perfectly separate from the body of the journal.

Archives de Physiologie. Publiées par MM. BOUCHARD CHAUVÉAU and MAREY, 5ème Série, T. vii., No. 2. Avril, 1895.—The chief articles contained in this number of the *Archives* are: 1. Experiments on Pancreatic Diabetes and

the Mechanism of the Regulation of Normal Glycæmia, by M. M. Kaufmann. In this article M. Kauffmann shows that the division of the nerves of the liver does not materially modify normal glycæmia, and that some material is produced by the pancreas which either acts directly on the liver or on the tissues generally. 2. A Study of the Auscultation of the Respiratory Apparatus, by M. E. Castex. In this memoir the author endeavours with some success to give a scientific explanation of the various respiratory sounds. 3. Researches on the Mechanism of Organic Oxidations, by MM. J. E. Abelous and G. Biarrès. 4. New Researches on the Influence of Intra-vascular Injections of Peptone on the Coagulability of Blood in the Dog, from which it appears that in dogs rendered immune against the anti-coagulating power of peptone the intravenous injection of this albuminoid no longer prevents the coagulation of the blood, because the organism of these animals no longer secretes under the influence of the peptone the substance which renders the blood incoagulable, and which probably proceeds from the liver or the intestines, by M. Contejean. 5. On the Variations of Temperature and of the Degree of Vaso-dilation in Diphtheritic Intoxication Artificially Induced, by MM. J. Courmont and M. Doyon. 6. Variations in the Virulence of the Poison of the Viper, by MM. C. Phisalix and G. Bertrand. Variations were observed which were associated with the locality where the viper was found and the season of the year in which the poisons—echidnase and echidnotoxine—of the viper were injected. 7. On the Mode of Action of the Nervous System upon the Production of Hyperglycæmia, by M. Kauffmann. 8. On the Elimination of Iron by the Urine, by M. Louis Lapicque. 9. On the Innervation of the Thoracic Duct, by MM. L. Camus and E. Gley, showing that this duct receives both constricting and dilating nerves from the great sympathetic. 10. On the Variations of Blood-pressure in the Veins, by M. C. Dalezanne, showing the very curious inverse relation which exists between the pressure in the renal and femoral veins. 11. On the Influence of the State of Sensibility of the Stomach on Gastric Chemistry, by MM. Paul Sollier and E. Parmentier. 12. On the Effects of Total Extirpation of the Stomach (in the Cat), by MM. Carvallo and V. Pachon. 14. Effects of Thyroidectomy in Reptiles, by Dr. H. Cristiani. 15. On the Toxicity of the Urine after Thyroidectomy, by Dr. Paul Masoin. 16. On Inhibition of the Tone and Movements of the Stomach in the Dog, by M. Maurice Doyon. 17. Trophic Changes in Cells dependent on Bacterial Secretions, by M. A. Charrin. 18. Fibrinolysis, by M. A. Dastre.

The Journal of Physiology. Edited by M. FOSTER, M.D., F.R.S., and J. N. LANGLEY, F.R.S. Vol. XVII. No. 6. April, 1895. London: Clay and Sons.—The principal contents of this part, in addition to the short accounts of the Proceedings of the Physiological Society, are:—(1) J. W. Pickering: Notes on the Action of Chloro- and Cyalo-caffeine; (2) J. A. Menzies: On Methæmoglobin, with a plate, and (3) on the Action of Certain Acids on Blood-pigment; (4) Dr. Sydney Ringer and Arthur G. Phear: the Influence of Saline Media on the Tadpole; (5) E. Waymouth Reid: Electrical Phenomena during Movements of the Iris, with an illustration; (6) Dr. Archibald Garrod: A Contribution to the Study of Uroerythrin, with a plate; (7) Arthur Edmunds: the Effect of Saturating Normal Urine with Certain Neutral Salts; (8) W. T. Porten: the Path of the Respiratory Impulse from the Bulb to the Phrenic Nuclei, with eleven illustrations.

The Ophthalmic Review. Edited by Mr. J. B. LAWFORD, Dr. MACLEHOSE, Dr. GROSSMANN, Mr. PRIESTLEY SMITH, Dr. JOHN STORY, and Dr. EDWARD JACKSON. London: J. & A. Churchill.—This number contains a paper by Mr. Ernest Maddox, entitled Simple Optical Notes, in which a useful method of testing the strength of concave glasses is given, followed by an interesting note on the Aberration of

the Eye. Dr. W. George Sym describes a case of Lenticulus Posterior, and Mr. James W. Barrett records a case of damage to vision caused by watching an eclipse of the sun.

Analytical Records

FROM
THE LANCET LABORATORY.

(1) FERRATIN. (2) LACTOPHENINE.

(C. F. BOEHRINGER & SOHN, W. ALDRICH, NEAR MANNHEIM. LONDON: DOMFIER & CO., 13, ST. MARK-HILL, E.C.)

FERRATIN is being introduced as a new iron derivative of acid albumen which may be obtained by extraction from pig's liver. It is, however, artificially prepared from egg albumen and chemically pure iron salts held in alkaline solution. Both artificial and natural ferratin occur in the form of a fine powder of rusty colour, odourless and tasteless. It contains 7 per cent. of iron, and it does not act injuriously, it is stated, on the teeth, while it is rapidly absorbed and said not to interfere with the digestive functions. The specimen we examined proved very slightly soluble in water, the solution being of a pale-yellow colour, which, when agitated, frothed in identically the same way as solutions of egg albumen. On adding hydrochloric acid to the powder, perchloride of iron is at once formed, and albuminous flocks are thrown out. On adding caustic soda to this acid liquid the reverse action takes place—that is, the iron is thrown out as perhydrate, and the albumen dissolves to form albuminate. Heated on platinum foil, ferratin emits a powerful smell of burnt feathers, and after a time pure ferric oxide remains. The constitution of ferratin is sufficient reason for believing it to be the greatest service in anæmia and other conditions of blood impoverishment in which iron is indicated, and we are hardly surprised to learn on this score also that excellent clinical results of its use have been recorded.

Lactophenine is described as a new antipyretic and anti-neuralgic, acting in general like phenacetin, but possessing over the latter the additional advantage of a permanent soothing effect. It is a phenetidine, being a lactic acid derivative of para-phenetidine, in which the acetic acid attached to the ammonia residue has been replaced by lactic acid, so that it might be properly called lactylphenetidine. It is a white crystalline powder not unlike phenacetin, sparingly soluble in cold but freely soluble in hot water, from which it crystallises on cooling. Like antipyrin and phenacetin, it is said to cause a rapid reduction of the temperature of the body, especially when it has been artificially raised. At the same time, however, lactophenine produces a state of hypnosis and diminishes considerably the sensitiveness to painful influences. In rabbits, even sensation and voluntary movements may, according to Dr. Jaquet,¹ be completely abolished, and the reflex excitability nearly so, without respiration and heart action being perceptibly affected. Although phenacetin has a similar soothing effect, it appears to be exerted to a much greater degree when lactophenine is substituted, the effect observed on animals calling to mind a urethane narcosis. It has been used with good effect as an analgesic in migraine, nervous headache, rheumatic trouble, and in the neuralgia of influenza.

BEEF EXTRACT TABLETS.

(J. CHRISTIE RENNICK, BOND COURT HOUSE, WALBROOK.)

These tablets will be found convenient for the extemporaneous preparation of soup. It is particularly satisfactory to find that the maker is alive to the great importance of using meat fibre as alone affording in a preparation of this

kind a source of nourishment, the extractives of beef serving merely as stimulant and restorative, much in the same way as a mixture of spirits and water. Microscopic examination thus revealed the presence of muscular fibre. Analysis gave the following results: moisture, 18.30 per cent.; meat extractives and fibre 75.8 per cent., containing 11.13 per cent. nitrogen; ash, chiefly phosphate, 5.90 per cent. The tablets represent, therefore, a concentrated and convenient form of food, each (1 oz.) being sufficient to make on simply stirring in boiling water for about five minutes one pint of good, palatable, and nourishing soup.

(1) MALT EXTRACT JELLY (MALTO-PEPTONE).

(2) MALT EXTRACT JELLY (MALTO-PEPTONE) WITH COD-LIVER OIL.

(MALTO-PEPTONE CO., 101, LEADENHALL-STREET, E.C.)

The sticky consistence of malt extract preparations, excellent though they are in all other respects, has undoubtedly proved an obstacle to their exhibition in many instances, and the presentation, therefore, of these valuable therapeutic agents in the form of a firm and attractive-looking jelly is a fact which many practitioners will welcome. We have recently submitted to examination specimens of both malto-peptone malt-extract jelly, and the same combined with cod-liver oil, with very satisfactory results. We find that the jellification process does in no degree affect the standard malt value of the preparation—indeed, the degrees of concentration and of digestive activity are not in the least respect inferior to malt extracts of established repute, although it is evident that some small quantity of a jellifiable substance must be introduced to make a jelly of the extract. This is substantiated to some extent by the fact that in our experiments we succeeded in separating a small quantity of gelatine. We regard this improvement as an introduction in practical medicine of considerable importance, since it is calculated to induce the easy acceptance of a valuable remedial agent the stickiness of which frequently proves obnoxious to many patients.

FERRET BRAND POLISH SOAP.

(GRIMER, MORTON, AND GODDARD, BOTOLPH HOUSE, EASTCHEAP, E.C.)

The combination with soap of a mechanical detergent is very effective both for cleansing and polishing purposes. This is broadly the basis of Ferret brand soap, since on treatment with boiling water a clean, white, insoluble silicious residue may be separated, while soap enters into solution. It is obviously useful for a variety of purposes, amongst which may be reckoned the cleaning of the door-plate and of harness; it does its work well.

KATHREINER'S MALT COFFEE.

(C. M. PATTENHAUSEN, 40, GREAT TOWER-STREET, E.C.)

While we are not disposed to admit some of the statements contained in a pamphlet relating to these preparations—as, for instance, that “coffee is one of the greatest evils that exist” because it contains “a rather considerable portion of the strong poison caffeine” (or coffeine, as it is misspelt)—yet coffee substitutes are doubtless acceptable, assuming of course that the flavour and aroma are equally pleasing, to not a few who cannot tolerate, through some susceptibility, the original article. The above preparation seems to us to have really secured these advantages for the first time. It consists of dark-brown malt berries, sticky to the touch and exhaling the agreeable aromatic smell of freshly roasted coffee. About one-third part is, we find, soluble in hot water, yielding a pleasant-tasting liquor very closely resembling genuine coffee infusion. As a result of roasting, much of the original starch of the malt has been converted into dextrine (torrefaction), while part of the albuminous substances is no doubt to some extent changed into certain aromatic bodies. The decoction may be regarded as possessing dietetic properties superior to coffee, for

¹ Correspondenzblatt für Schweizer Aerzte in Basel.

it contains part of the nourishing constituents of malt; but in regard to stimulating effects it can obviously possess no value referable to caffeine, although it is very probable that certain other stimulating substances are developed during the roasting process. On the whole, therefore, we regard the preparation as a probably valuable addition to this class of beverage and food; it is certainly a satisfactory coffee substitute.

FAVARA'S JUICE OF THE GRAPE (MOSTI DI SALUTE FAVARA).

(O. FAVARA AND CO., 52, LEADENHALL-STREET, E.C.)

This preparation is described as consisting of the juice of grapes pressed out of the sweet ripe grapes in the cold by a special process and then concentrated. It is a dark-red somewhat viscid fluid, which when diluted with water possesses the peculiar sweet and agreeable flavour of the dark variety of grape. It is said further to be sterilised, non-alcoholic, and unfermented. This we quite believe, although it is not surprising that in our analysis we found a small proportion of alcohol. Thus, on distillation the density of the distillate proved to be 0.9983, which would be equal to 0.89 per cent. alcohol by weight, 1.13 per cent. by volume, or 1.97 per cent. proof spirit in the original fluid. The expressed juice of the grape is, of course, so susceptible to fermentative change that it would be remarkable to find it absolutely free from alcohol. As will be seen, however, the quantity is small and quite negligible on "temperance" grounds. The solid matters, amounting to 65.16 per cent., consisted chiefly of grape sugar and the characteristic constituents of the fruit; the mineral matter, amounting to 0.83 per cent., was quite reddish-brown from the presence of a marked amount of iron, and contained also carbonate, sulphate, and phosphate of potassium. There can be little doubt, therefore, of its genuineness, and, that being so, it may be regarded as offering in some degree the tonic and invigorating properties for which certain pure wines are esteemed. It is satisfactory to add that we obtained no evidence of injurious preservatives having been employed.

PINOZA CIGARETTES.

(LUSBY'S PINOZA TOBACCO CO., 10, MINORIES, E.C.)

The fact that the inhalation of pure pine oil is sometimes attended with benefit in certain affections of the respiratory organs has doubtless led to the idea of impregnating tobacco with the oil to effect, in a more or less agreeable way, the same thing. The Pinoza cigarettes yield a tolerable amount of oil when submitted to the action of a current of steam, the oily drops separating from the condensed water. When smoked the presence of pine oil in the mouth is unmistakable, and is not at all disagreeable. It may be true that pine oil volatilised in this way would exert a soothing effect, but we are inclined to think also that the tobacco at the same time would lead to irritation in cases of sore-throat and bronchial catarrh. The cigarettes burn remarkably well despite the presence of the oil, and the tobacco employed is obviously selected especially for the purpose. Pinoza cigarettes are also made containing a much larger proportion of oil.

(1) STANDARD MALT EXTRACT.

(2) STANDARD MALT EXTRACT AND COD-LIVER OIL.

(THE STANDARD MALT EXTRACT COMPANY, 23, BILLITER-STREET, E.C.)

It is quite admissible to apply the word "standard" to this preparation, inasmuch as we find it possesses a remarkable degree of digestive activity, being stronger in this respect than many preparations we have previously recorded. Nor is its high diastasic power gained at the expense of taste, which is excellent, being entirely free from that acidity and burnt flavour which not infrequently characterise similar preparations. This extract, as might be expected, affords an excellent vehicle for the administration of cod-liver oil, the same company's preparation representing this combination

appearing as a true emulsion under the microscope, while its taste, which is pleasantly aromatic, is acceptable.

HYGIENIC COFFEE.

(THE LONDON HYGIENIC DEPOT, 68, LAMB'S CONDUIT-STREET, W.C.)

We find that this preparation is regarded as hygienic because it contains neither *caffeine* nor chicory. It consists of a dark-brown branny substance, which doubtless yields a nourishing and wholesome enough infusion, but we cannot speak favourably of its flavour, which compares very indifferently with the agreeable aroma of freshly ground coffee. The statement that it is free from caffeine and chicory is correct, our attempts to extract the former by well-known methods being futile.

SUNFLOWER COCOA ESSENCE.

(SUN COCOA AND CHOCOLATE MANUFACTURING CO., LIMITED, NEWCASTLE-STREET, ALDGATE, E.C.)

A superior-grade cocoa free from added starch and sugar. It yields 4.20 per cent. mineral matter, of which 1.40 parts are soluble and 2.80 parts insoluble in water, while the alkalinity of the soluble portion is equal to 0.56 per cent. K_2O . There is no evidence, therefore, of the use of alkali to render the cocoa so much more "soluble."

New Inventions.

A SUPPORT FOR THE KNEE-JOINT.

A NEW pattern of support for the knee-joint has been recently brought out by Mr. J. H. Haywood, surgical appliance manufacturer, Castle-gate, Nottingham. It consists of two flexible steel bands, well padded, and secured by straps and buckles, which encircle the limb above and below the joint, and are connected by flat-jointed steel rods extend-

ing on either one or both sides of the knee, as may be necessary. In ordinary use these joints move freely, but when fixation of the knee is required they can be made rigid. It is claimed for the apparatus that it can be adapted to cases of fractured patella, and that it supports the joint without the chafing and constriction occasioned by knee-caps of other materials, such as leather. It is easily put on and taken off, either under or over the trousers, and in this respect will be useful to miners, labourers, railway men, cyclists, &c. It can be readily cleaned, it is inexpensive, and very durable.

THE PATENT PNEUMATIC VACCINATION SHIELD.

THIS is an annular cushion made of very thin indiarubber and inflated with air. The central aperture is about an inch and a half in diameter, and the thickness of the ring is about half an inch. It is extremely light and soft and is provided with three ribbons, two of which are tied round the infant's arm and the third is fastened to the sleeve of the clothing. The makers are Cole's Pneumatic Shield Company, Limited, 79, Lower Gardiner-street, Dublin.

THE LANCET.

LONDON: SATURDAY, APRIL 27, 1896.

THE probable production in man of tuberculosis having its origin in food from tuberculous animals is a question of perhaps more immediate importance to preventive medicine than any other of the numerous public health aspects of tuberculosis. We have never held that a complete solution of the many problems of this disease in man is to be found in his opportunities of infection, and we have been led to look with some reserve upon recent advocacy of preventive measures apparently based on a restricted view; but clearly if infective tuberculous matter is demonstrated to exist with any degree of frequency in food, and to be dangerous to human consumers, we have to deal with a condition of great moment to the health of the country. The issue of the report of the Royal Commission on Tuberculosis will, therefore, be studied with considerable interest. For some time prior to the appointment of the Royal Commission it had been felt by sanitarians that a careful examination of the facts would show that a regulation of our food-supply *quâ* tuberculosis was urgently demanded, and that in this matter we were already far behind the practice of public health organisations on the Continent; while, on the other hand, stock owners and others engaged in the meat and milk trades were complaining that in districts where tuberculosis was dealt with they were suffering considerable hardships for an object they scarcely understood and which they were disposed to think fanciful. Accordingly a commission of experts in public medicine and agriculture was appointed in 1890 under the chairmanship of Lord BASING, and was reorganised last year under that of Sir GEORGE BUCHANAN. We publish elsewhere an abstract of the carefully reasoned report now issued. As might have been anticipated, it leaves no room for doubt that "the actual amount of tuberculous disease among certain classes of food animals is so large as to afford to man frequent occasions for contracting tuberculous disease through his food," and states the Commission's belief that an appreciable part of the tuberculosis that affects man is obtained through food. Accepting this position as demonstrated by the inquiries referred to in the report, we would now draw attention to some of the circumstances and conditions under which this potency for harm is found to exist. As regards meat—we note that beef is principally in question—we find that the Commissioners consider that of the dangers in the dressed carcass afforded respectively by tuberculous organs unremoved, by minute tubercle in or among muscle substance, and by contamination of the surface of the meat (it may be of healthy carcass) with tuberculous matter brought by the knives and cloths of the butcher in the process of dressing, the last is much the most considerable; and they point out that, provided all tuberculous parts are removed and care is taken to secure the meat substance from contamination in dressing, a great deal of meat from tuberculous animals may be consumed without risk. The risk cannot be removed with any certainty by cooking, for tubercle in the tissues

away from the surface does not lose its infectiveness in any process of cooking, neither does the tuberculous matter originally smeared on the surface that comes to be included in the centre of meat made into rolls. As to milk in the next place, the report carries conviction that there is one condition necessary for it to be infective—namely, that it must come from a cow with tuberculous disease of the udder. The Commissioners point out the means of recognising this disease, and draw attention significantly to its rapidity of onset and to its occurrence in any stage of tuberculosis in the cow; and with regard to the extreme virulence of milk, even diluted, from such a cow the reader of the report can have no doubt whatever.

The facts ascertained by the Commission are, perhaps, hardly unexpected, but they now rest upon a secure basis of inquiry and experiment. And we turn with some anxiety to consider the public health aspect of its report. In the interests of the health of the community, and particularly of children, it is clearly the duty of the State to deal with the question thoroughly. We do not minimise its administrative complexity. The problem of ensuring in practice the detection of tuberculosis in milch cows and prompt action in cases of tuberculous udder disease is by no means free from difficulty. And still more difficult is it to ensure safety in meat if it can only be obtained by skilled supervision of the operations of slaughtering and dressing. For although this report adds weight to the rightly increasing demand for public abattoirs (in which alone can the needful supervision be secured), yet it is clear that provision of them would not deal with the large class of "dead meat" that might be extensively contaminated before its importation. Nevertheless, the danger to public health shown by the Commission to exist admits of no neglect, and there can be no question that much can be done to lessen it in this country—indeed, we have only to look to the regulation of food supply in Germany and Denmark to see how much may be and already has been done in this direction. Of one thing we are convinced, that no efficient action can be taken on this question unless it is pursued on a carefully planned administrative policy, adequately advised and controlled from its medical aspects. Such policy can only be carried out by a medical department of the State. For the State tuberculosis as it affects human health must cease to be something totally different from tuberculosis as it affects cattle, and in this, as in other cases, matters vitally affecting the health of the kingdom should not be made a matter for any public department to slur over when it finds itself confronted with the question.

DR. GLOVER's address at the North London Medico-Chirurgical Society, which we published in THE LANCET of April 20th, presents many points of interest. Most of his hearers would appreciate his judgment in leaving to men of special training the discussion of such subjects as the methods of bacteriology, and in choosing for his theme the work and prospects of medical practice. As a general practitioner he could not but enter somewhat deeply into questions affecting the relation of consultants to members of his own section of the profession. Needless to say, he does not forget what is due to either party. The opinion

expressed by Sir WILLIAM LAWRENCE that pure physicians would soon become obsolete in London is not shared by Dr. GLOVER. As he truly observes, while the medical wants of mankind remain the same as now there will be the same demand for medical service in its different forms and grades. There is, nevertheless, a certain truth and force in the saying of the eminent surgeon already referred to, and Dr. GLOVER shows how the extension of scientific medical teaching and its universal similarity tends inevitably to level the distinctive barriers once existing among medical men. There are some who would reduce the outflow of knowledge intended to meet the requirements of young men about to engage in general practice to a current of considerably less volume than the liberal provision to be placed at the disposal of a coming consultant. We are not of their number, nor, we observe, is Dr. GLOVER. On the contrary, he hails the advent of a period in education when any and every student is understood to acquaint himself with the elements of all the specialisms. A knowledge like this, at once general and particular, must of necessity greatly strengthen and extend the utility of its possessor. It represents so much clear gain to general practice and through this channel to the public, especially to that larger section of it whose means are limited. It must also in a degree, by engendering a habit of self-reliance, render the modern practitioner to some extent independent of professional allies. This is even more true in its application to the medical than to the surgical department of practice, inasmuch as diseases which are usually included within the province of the physician are more frequently met with than are at all events any but the minor occasions for surgical interference. After making every allowance, however, for the natural and right exercise of this result of better instruction there will remain a large margin of doubt and of difficulty in connexion with the duties of the profession where the experience of consulting advisers will find its opportunities of service. The fact that it is aided at such times by the increased intelligence of both the consulting parties cannot but greatly enhance its practical value to the sick. There is an irregular variety of specialism, if we may so describe it, with which it is imperative for the general practitioner to be well acquainted—the knowledge of common and trivial diseases. Dr. GLOVER has done well to call attention to this subject. A revival of the system of pupilage, in his opinion, constitutes one of the best methods of ensuring an acquaintance on the part of young medical men with this wide field of professional responsibility.

The relation of the public as a whole and of the State to the medical profession was discussed at some length by Dr. GLOVER. It is characterised, he observes, by a close and growing intimacy. There is here indeed, as he says, no tendency to medical disestablishment, but rather the reverse. Unfortunately for the medical side of this partnership no feasible scheme of endowment or remuneration for services rendered appears as yet to have been imagined. What movements of justice, gratitude, or remorse may have stirred the corporate mind of the central government it would be rash to suggest. On one point our own view has long been clear—namely, the advantage to the State itself of the adequate representation of the medical profession in both Houses of

the Legislature. We have seen that there constantly arises in the conduct of ordinary medical practice the necessity for an interchange of views between those who are concerned with the treatment of disease. Where the State intervenes, as it oftentimes must in the interest of public health, a similar necessity arises. It becomes *de facto* the custodian of public security in relation to disease. Its attitude in this case if it be deprived of professional medical advisers would be in the highest degree irrational. If, then, such advisers are so essential a part of its administrative machinery, what, we would ask, is more natural or more needful to the commonweal than that the position of these medical advisers should be fully recognised and their aid in counsel rendered secure, constant, and inalienable by such acknowledgment?

Dr. GLOVER, during the course of a professional career which began forty years ago, has seen many changes, both in our conceptions of morbid phenomena and in our modes of treatment. It would be superfluous to describe these in detail. They now form part of the solid fabric of medical science, the articles of a creed which is no merely empirical dogma. We pass on to read the lesson which with him forms the appropriate conclusion of much excellent matter—namely, that the contact of minds in social intercourse and in our common work and duty of clinical observation keeps our knowledge fresh. It is the general practitioner's misfortune that the necessities of his ordinary duties allow so little leisure for the study of problems in the treatment of disease. We are certain, however, that in proportion to his interest in this field of research, if it be duly translated into action, will be his success as a practitioner. The importance of maintaining a right relation towards all professional brethren requires no comment. Both ends are most happily served by a connexion with medical societies. Their value has long been recognised by members of the profession, though not always sufficiently, perhaps, by general practitioners. We would, therefore, the more strongly recommend such associations to these latter, who should not only belong to them, but should take active part by furnishing clinical cases, notes, or other material for discussion at the periodical meetings.

IN another part of our present issue we publish an address by Dr. CHAMPNEYS, which discusses at length the matters in dispute between the Obstetrical Society and the General Medical Council. Dr. CHAMPNEYS speaks as the President of the Society, and therefore with authority. It will be well to try to make clear the views which he expounds and to see how far they accord with those of the General Medical Council. This is the more necessary as the General Medical Council will meet towards the end of May, and the adjustment of any differences will be a portion of the business of the Council. In a few words, Dr. CHAMPNEYS may be said to rely on the following propositions for supporting his defence of the action of the Society in supplying those women who pass its examination with "diplomas" testifying to their "skill" in natural labour. His points are as follows:—

Midwives exist and have existed from the beginning. The question is not whether midwives shall exist, but whether they shall be as bad or as good as possible. Dr. CHAMPNEYS

maintains that the difference means an immense difference in the well-doing of lying-in women and their children. The action of the Society was the result of an investigation into the causes of great infantile mortality, especially of newborn infants, suggested by Dr. FARR. This investigation showed that from 30 to 90 per cent. of the poor in villages were attended by midwives; and secondly, that the midwives were not instructed. The action of the Society is perfectly disinterested, as is shown by its constant efforts to hand over the work of examination and certification to a body authorised by law for the purpose. The examination and registration of midwives have been carried out under legal sanction in nearly all foreign countries and have been aimed at in some form in our own country since 1616 when PETER CHAMBERLEN begged the same of JAMES I. The Medical Council and the medical press have advocated such a policy. Such examination will best keep midwives in their proper place and check all irregular practices on their part. Dr. CHAMPNEYS denies that the interests of the profession are affected by the creation of a class to attend the poor for a few shillings. The form of words and the diploma have not been adopted without the advice of the solicitor of the Society.

Our readers would do well to read for themselves the condensed report of the address itself, and of the correspondence which has passed on the subject between the Council—or, rather, its Executive Committee—on the one hand and the Society on the other. The duty of the Council is very simple. It is an executive body, created for administering Acts of Parliament, the chief object of which is to supply the public with duly qualified practitioners, and “to enable persons requiring medical aid to distinguish qualified from unqualified practitioners.” Here is a very literal and a very responsible duty from which the General Medical Council cannot escape even if it would. It cannot be indifferent to any action on the part of registered members of the profession—over whom alone it has any jurisdiction—who do anything calculated to confuse the distinction between qualified and unqualified practitioners. It is inconceivable that the Obstetrical Society or its distinguished leaders should intentionally or knowingly do anything of this sort. To their own minds and to the minds of the General Medical Council, or to the mind of a lawyer, it is obvious that the document given to a midwife who has passed the Society's examination has no legal character, and that the woman who has it has no legal advantages over the woman who is without it. But it is undoubted that in giving an imposing-looking document, calling it a “diploma,” and guaranteeing the quality of “skill” in the possessor of it they convey to many of those whose interest it is to know the difference between “qualified and unqualified practitioners” an impression that she is a qualified person. Such persons are of the poor and uneducated classes—the classes that use midwives. It is unmistakable that on them such an impression is made. Not only so, it is within our knowledge that it is made on some of the women themselves who receive the document, and they draw a distinction between the certificate which they get from a lying-in hospital and the “diploma” they receive from the Obstetrical Society. We have no doubt that those who framed the diploma of the Obstetrical Society did not anticipate that the words and character and name of their paper could produce such an impression; but now that the point is raised and pressed it would be strange if they did not cheerfully and earnestly meet the

wishes of the Council by altering the wording of the document. The correspondence they have published shows their disposition to do so, and we shall be disappointed if before the General Medical Council meets the difference is not adjusted. The Council cannot be charged with indifference on this subject. It has felt its own responsibility and has expressed very definite opinions. But that is no reason why it should not insist on mere amateur certificates being clearly distinguished from documents conferring legal privileges and advantages. The members of the Obstetrical Society will admit that the great improvements in midwifery date from the time when it was brought into line with the other great branches of medical science—medicine and surgery. Once dissociate it from these and from the great principles of hygiene and therapeutics, and the mortality and misery of lying-in women would be quadrupled. The midwife is not a practitioner. She is a special nurse acting under the direction and supervision of the medical profession. It has been our contention throughout that provision should be made in every parish for the poorest person attended by a midwife in any irregularity of labour to have the immediate benefit of a qualified practitioner. We are glad to see that this is Dr. CHAMPNEYS' own view, for he says (the italics are ours): “*A system by which midwives in a district should be placed under the direction of a leading local practitioner would be beneficial to the poor and to midwives.*” We should then cease to hear complaints of midwives acting as medical women.” We look forward hopefully to the settlement of this dispute without hardship to lying-in women and without any concession of the principle that in the long run the poorest lying-in woman is to have the benefit of a fully qualified medical practitioner.

Annotations.

“*Ne quid nimis.*”

HOSPITAL PATIENTS AND IMMORALITY.

AN extraordinary statement was published in many of our contemporaries on Sunday last that “the number of patients attending the London hospitals would be reduced quite 60 per cent. if the people developed the power of self-restraint and self-control.” This statement is said to have been made at a meeting of the Young Men's Christian Association on the preceding evening by Mr. Albert Carless, M.B., M.S., assistant surgeon to King's College Hospital. He is further stated “to have referred to a continual increase of immorality, and claimed that the result was being felt in a very noticeable manner in all London hospitals.” Such a statement by a responsible officer in one of our great metropolitan hospitals, unless made on accurate statistics, is much to be deplored, as it must tend to check the contributions of the charitable and to lead to many anxious inquiries by the subscribers and donors to our hospitals. Will Mr. Carless explain how he arrives at this percentage among the patients treated at his own hospital as well as at the other great metropolitan hospitals? Mr. Carless, in seeing out-patients at a hospital where no fees are charged, will, of course, prescribe for a large proportion of venereal diseases; but has he not forgotten the large number of non-surgical out-patients, the casualties, the special affections, and the in-patients, which are daily attended in his and

the other great general hospitals? There are no statistics bearing on these points in the recent issue of the reports of King's College Hospital or in those of any other hospital, and we fail to find any justification for such a sweeping assertion. The recommendations of Mr. Carless to the young men of London are well advised, but such unguarded statements by an important medical officer at a leading hospital will do great injury to such institutions, and should not have been made unless there is statistical evidence forthcoming to prove their accuracy. Has Mr. Carless this evidence? If he has, would it not have been better, in the interests of hospital management, for him to have submitted it to the committee of his hospital with some practical suggestions, rather than have given publicity to such opinions at a meeting at Exeter Hall, where they could not be gauged, corrected, or verified?

THE PRIVATE HOSPITAL CASE.

THE injunction sought by the Earl of Pembroke to restrain the defendants from using the house which they had purchased in Fitzwilliam-square, Dublin, as a private hospital has been granted. That the matter was important and the arguments intricate may be deduced from the strength of the Bar employed, which included no less than eleven counsel of high position, as well as from the time occupied by the case. The house in question was leased by the late Earl of Pembroke to a Mr. Warren, from whom the defendants held it as sub-lessees. The original lease contained a covenant which enumerated several trades or businesses which should not be carried on in the house, and concluded with the words "or any other offensive or noisy trade, business, or profession whatsoever." The whole case turned on the interpretation of these "general words," and the question whether a hospital came within them. It has now been decided in the affirmative, and this square, the houses in which are all similarly circumstanced as regards lease, is well-nigh secure against intrusion on the part of hospitals. It is, however, possible that the defendants may take the opinion of the Court of Appeal on the matter, and the Vice-Chancellor in making the order for the injunction decreed that it was not to come into operation until June 1st, in order that an opportunity of doing so should be afforded.

OVERCROWDING AND UNDERSTAFFING AT ISLINGTON INFIRMARY.

SOME of the Islington guardians are, it appears, by no means pleased at being reminded of the overcrowded and unsatisfactory condition of one of the chief institutions under their care, and they do not accept in the spirit in which it is offered the counsel of the Local Government Board. From a recent report of one of the Board's inspectors it would seem that there are, or were, in the infirmary no less than 168 patients over the certified number, while in the workhouse, which is itself overcrowded, are 160 sick inmates. In addition to this, we are told that the medical staff is inadequate, the nursing staff too small, and the accommodation meagre. This is certainly a somewhat appalling category of the omissions, if not commissions, of the guardians past and present; and we are glad to see that Sir Walter Foster spoke in no uncertain terms to a deputation of the guardians which recently waited upon him as to the course they should pursue, even though it necessitated a very material expenditure. The guardians, it is said, recognise the necessity of further accommodation, and they have at the present time two schemes before them, one for erecting a new infirmary at Bowes Park at an expenditure approaching £200,000, the other for enlarging the present accommodation at St. John's-road at a cost of about £50,000. It was in connexion with this latter scheme that the deputation above referred to waited upon

Sir Walter Foster, and commenting upon his observations at that interview one of the guardians is reported to have said that his "language towards the deputation was disgraceful," and that "he had told them not to consider economy, but to squander thousands of pounds to maintain officialism." This guardian's remarks most certainly have afforded some amusement to his colleagues. What connexion there is between providing accommodation for the sick and infirm of Islington in keeping with the spirit of the times and "officialism" we fail to see; nor is it clear why expenditure so incurred should be regarded as "squandering." We imagine, however, that the guardians as a whole do not share the opinion of their colleague, but that they will recognise the necessity of facing this important question and of dealing with it in a broad and comprehensive manner, and not in such a way as to require frequent alterations, tinkering, and deadlocks. A new infirmary will, we are fully aware, occupy considerable time in building; but in the meantime we trust that the guardians will not postpone the necessary additions to their staff or wait until some serious accident brings scandal upon the institution.

EXPERIMENTS ON NORMAL SLEEP.

AMONGST the numerous papers that were read, or were taken as read, at the International Congress at Rome last year, and which now appear in the first volume of the Reports (or "Atti") just issued to members, is one by Professor I. Tarchanoff of St. Petersburg, who has made some experiments on sleep in puppies varying in age from three weeks to three months. At this age the animals have a strong disposition to sleep—sleeping even when the brain is exposed for experiments on the motor area, or when the carotid is exposed to enable the blood-pressure to be taken, or when they are exposed to cold and fasting; under any of these conditions the act of stroking the head and back for a few minutes will ensure the supervention of sleep; adult dogs, on the contrary, will not thus sleep unless some narcotic has been administered. Position of the body exerts a distinct influence. Thus puppies lightly strapped to a plank were placed some in a horizontal and others in a vertical position, and of the latter some were held with the head downwards and others with the tail down. It was found that stroking and caressing only failed to induce sleep when the head was downwards. In accordance with this was the fact that the excitability of the cortex of the cerebral hemispheres, and particularly of the psycho-motor centres, notably diminishes during normal sleep, so that a test electrical current which when the animal was awake was quite sufficient to excite movements, after it had been put to sleep by stroking had to be strengthened by several—sometimes as much as ten—milliampères to produce the same effect. Experiments made under the same conditions, when the carotids were exposed and connected with a kymograph, demonstrated that the arterial pressure fell during sleep from twenty to fifty millimetres, and that when the animal woke it returned to its former height. These facts are quite in accordance with the statements and observations of Mr. Durham that the brain is anæmic during sleep. Further experiments were made by Prof. Tarchanoff on animals, in which the spinal cord was divided between the dorsal and lumbar regions, from the immediate effects of which injury the animals had recovered. Prof. Tarchanoff set himself to ascertain what the effect of the section was on the reflex acts of the posterior paralysed limbs, as compared with the corresponding acts of the anterior unparalysed limbs. The stimulus applied was the induced current of a Dubois-Reymond's induction apparatus applied by means of needles embedded in the skin, and the results obtained were that whilst the duration of the reflex

acts in the posterior limbs, innervated by the lumbar portion of the spinal cord, remained unchanged during sleep, that of the anterior extremities innervated by the spinal cord and brain underwent a notable depression during sleep, so that on some occasions the current, previously effective, required to be considerably strengthened before any reaction occurred. Hence Prof. Tarchanoff, using the same phraseology as that long ago employed by Marshall Hall, observes that "the spinal cord never sleeps." He thinks, further, that the brain is not during sleep inactive in all its parts, but is, on the contrary, a source of a depressor action propagating itself to all parts of the cord which are in perfect continuity with the brain.

INCREASED REMUNERATION OF DIVISIONAL SURGEONS OF THE METROPOLITAN POLICE.

WE are glad to be able to inform our readers that the Secretary of State for the Home Department has agreed to grant, on the recommendation of the Commissioner of Police, Sir E. Bradford, an increase in the rate of pay hitherto allowed to the divisional surgeons for their attendance on the members of the Metropolitan Police Force. This will in some instances amount to an important item at the end of the year.

COUNTRY HOLIDAYS FOR POOR CHILDREN.

A VERY beneficent work is being carried on by the Children's Fresh-Air Mission, which provides holidays in the country for juveniles from the poor districts of Holborn, Clerkenwell, and St. Luke's. Since 1882 there have been 26,000 little ones favoured in this way, the number last year being 3014. The localities resorted to are very numerous, Minster in Kent last year heading the list with 389 such visitors, and Stokenchurch in Oxfordshire coming next with 260. A fortnight is the usual duration of this happy change from the unwholesome courts and alleys of London to the green fields and lanes of the country, from which the youngsters return to their parents in improved health and spirits, and with an enlargement of their ideas on the subject of natural scenes and objects. The offices of the Mission are appropriately fixed at St. Peter's Schools, Onslow-street, Clerkenwell-road.

THE NEW STREET DANGER.

THE recent reports of Major Cardew on the circumstances connected with the comparatively new street danger arising from the firing of gas by electricity are by no means reassuring or calculated to allay public anxiety. We have absolutely no pledge that the conditions which led to the explosions and disruptions of the pavements in certain of our highways might not obtain elsewhere at any moment. In the last return, for instance, which deals with the Southwark Bridge explosions, Major Cardew finds it is difficult to account for the firing of the gas which undoubtedly was escaping from the gas mains, but he seems confident that it was not by means of the electric lighting mains, as there were none in the vicinity of the explosions. Other causes are consequently sought after, and a lighted match thrown carelessly away or a spark struck by a horse-shoe or wheel is suggested. In that case the question arises as to why explosions of this kind did not occur before electric lighting came into existence. The position, it seems to us, is practically this: electricity has brought to light the fact that gas mains are imperfectly laid down, so that in many instances they seriously leak; and in turn coal gas retaliates, so to speak, on its rival by showing that the mains through which it courses are not exempt from the same charge. It is a curious case of a *quid pro quo* between the two. Competition is looked upon as serving

best the interests of the public, but in this case we may claim some exception. "It must be admitted," Major Cardew says, "that the main cause of the Southwark explosions was the defect in the gas-pipe, and it again directs attention to the very serious danger to the public arising from the condition of the gas-pipes in many districts and the way in which they are laid and supported, a danger which is continually increasing owing to the spread of the use of wood paving and other impervious surfaces, and which is temporarily intensified by every severe frost. No remissness on the part of the gas companies can, however, relieve the Electric Lighting Company of the duty of thoroughly complying with Regulations 14 and 15 by sufficiently protecting their conduits and street boxes against an accumulation of gas." We repeat, the danger may still be lurking beneath our streets, and we earnestly appeal to the Board of Trade not to lose a single moment in compelling both gas and electric companies to take all the precautionary steps it is possible to take and thereby to remove a risk of a very serious kind from our crowded highways.

THE EFFECTS OF ABLATION OF THE STOMACH IN THE CAT.

IN the part just published (April, 1895) of the *Archives de Physiologie*, MM. J. Carvallo and V. Pachon give the results of an experiment upon the cat which they performed as a kind of control experiment to those made by other observers, as by Czerny and Kaiser, Filipi and Monari, in which the animal selected was invariably the dog. In the cat it is possible to practise complete gastrectomy, and in one of the cases recorded, in which the animal died after forty-eight hours, union between the oesophagus and the duodenum was found to be complete when the necropsy was made. In another case, in which the animal weighed two kilogrammes, it was living and healthy three and a half months after the operation, and then weighed two and a quarter kilogrammes. It was fed on milk and on a mixture of milk, yolk of egg, and rice. The digestion of milk alone was not perfect, the fæces being liquid and containing clots of undigested milk. The mixture of milk, yolk of egg, and rice was, on the contrary, perfectly digested, as were also fragments of cooked meat, of cheese, and a *purée* of potatoes. All three classes of aliment—albuminoids, fats, and farinaceous substances—were therefore digested in the agastric cat as perfectly as in the agastric dog. Vomiting only occurred on two occasions.

SCHOLASTIC REFORM IN GERMANY.

WE learn from a French source that an innovation of a somewhat peculiar nature has been adopted by the scholastic authorities in Germany. In future the pupils in all public schools are to be divided into two classes—the intelligent and the stupid. The brighter spirits comprised in the first category are to receive instruction in the higher branches of learning, whereas the dullards—once their mental inferiority has been finally adjudicated upon—will be taught the rudiments only. But, it may be asked, by whom is the line of demarcation to be drawn? Whose shall be the invidious task of separating the sheep from the goats? Now, although it is pretty well known that disagreeable duties of an extraneous character are frequently imposed upon members of the medical profession, still we imagine that the answer to the foregoing inquiry will come as a surprise to the majority of our readers. The differentiation between the youthful Teutons is not to be made by their own pedagogues, as might be supposed, neither is it to depend upon competitive examination. Medical men, general practitioners apparently, are to perform the selection, being credited with an ability to arrive at an authoritative decision after an inspection of each child's cranium and general physical development. Not only will they be required to discriminate, by virtue of

their physiological attainments, between budding geniuses and imbeciles, a comparatively simple undertaking—they will also be saddled with the responsibility of determining the fate of that far more numerous class whose mental capacity verges on mediocrity. The diagnosis of disease is by no means an easy feat, but inasmuch as the physician has all the necessary data before him, in one form or another, he may not unreasonably be expected to arrive at a correct conclusion. When, however, he is called upon to prophesy, as it were, regarding such a very problematical affair as the future development of a child's brain, his judgment must to a large extent be based upon conjecture. Dull children not infrequently grow up into brilliant adults, and *vice versa*. On the whole we are inclined to think that this, the latest of pedagogical innovations, is not likely to turn out a conspicuous success.

ANOTHER EXPLOSION AT WALTHAM ABBEY.

WHATEVER may be the practical advantages of cordite for ammunition purposes, there still comes evidence, unfortunately, of the fearful risk run by those engaged in its manufacture. It is reported that an explosion took place on Monday afternoon last at the cordite works, Waltham, where a full charge of 28 lb. of cordite was being pressed in a hydraulic press, which appears to be the essential part of a new compressing process. Two men and three boys were injured, the injuries of one of the former being very serious. The cause of the explosion does not appear to be known, but we are loth to believe that the strictest precautions are not taken to avoid the least possible chance of accident. The latest accounts, however, state that the explosion was due to the cordite becoming dry, owing to the press being left open during a "shift" of workmen. The results of the slightest negligence in the operations concerned in the preparation of powerful explosives of this class may have so serious a consequence and so far-reaching an effect as to demand the strictest supervision. It will be remembered that since the occurrence of a series of disasters which befel the operatives in the cordite factories at Waltham during the last few years a committee appointed to inquire into the matter recommended certain important changes in the management and organisation of the manufacturing processes. We trust that these recommendations were acted upon without the slightest delay.

CHANGES IN THE BLOOD IN YELLOW FEVER.

A MOST valuable and instructive series of articles on the Natural History (Symptoms and Pathology) of Yellow Fever by Dr. Joseph Jones of New Orleans is at present appearing in the *Journal of the American Medical Association*. In the issue of March 16th the condition of the blood in this disease is considered. That the blood undergoes profound changes during the period of febrile excitement of yellow fever is manifest even to the casual observer in the impeded capillary circulation, purplish, jaundiced, and dusky hue of the surface, livid blotches, passive hæmorrhages from slight abrasions, blistered surfaces and hæmorrhages from the ears, eyes, mouth, gums, and gastro-intestinal mucous membranes, which in some cases are characteristic of the succeeding period of calm or exhaustion. The changes of the blood appear to be continuous from the time of the introduction of the poison to the fatal termination. According to Dr. Jones the alterations of the blood in yellow fever consist chiefly in: 1. Such an alteration of the chemical and physical properties of the fibrin and albumen as leads to the transudation of the latter through the excreting structures of the kidney. 2. Various degrees of alteration and diminution of the fibrous element. In some cases there is an almost entire disappearance of this

element. This disappearance appears to be due to the direct action of the febrile poison and not so much to the action of ammonia. From this alteration in the amount and character of the fibrinous element it results that the blood coagulates imperfectly and the clot is voluminous and soft. 3. While the red blood-corpuscles are very slightly diminished in yellow fever they present under the microscope certain peculiar appearances, which appear to be referable to the action of extraneous matters in the blood. 4. Increase of the extractive matters of the blood. 5. Increase of the fatty matters. 6. Accumulation of bile in the blood in consequence of the profound lesions of the liver induced by the febrile poison, and in consequence of the failure of the excretory function of the kidneys. Many of the changes of the blood, as well as certain cerebral symptoms, may be dependent upon the presence and action of the biliary constituents. The serum presents a golden colour, this being due to the presence of bile. 7. Accumulation of the urinary constituents, and especially of the urea and phosphoric acid, sulphuric acid, chloride of sodium, and carbonate of ammonia, in the blood consequent upon the profound lesions induced by the febrile poisons and its products upon the kidneys. 8. Rapid dissolution of the coloured corpuscles after the blood is abstracted from the body either during life or after death. 9. Rapid putrefaction of the blood of those suffering from yellow fever after its abstraction from the living body or from the large vessels after death.

MILK FOR INFANTS.

MUCH as cows' and women's milks may vary in composition among themselves, as may also that of the same individual at different times, the essential distinction between the two milks lies in the larger percentage of casein in that of the cow and in the tougher consistence of the coagulum produced by the gastric secretion. The latter defect is to some extent overcome by malting, and the former may be adjusted to the infant's digestive powers by diluting the milk with water or by dividing the milk into two portions, coagulating the casein in one with rennet, removing the curd, and mixing them again. The former is open to the grave objection that dilution reduces the fat and the sugar, neither of which were in excessive amount, equally with the casein, and, though milk sugar and cream may be added, cream itself contains very uncertain proportions of fat and cannot again be perfectly incorporated with the milk, the fat globules having to some extent coalesced. In the latter process the proportions of fat and sugar are undisturbed; but it is tedious, and the tendency of the milk to "turn" is increased. Gaertner has recently taken advantage of the action of the centrifugal separator to retain in a diluted milk the full percentage of the fat. Fifty litres of fresh milk and the same of water are poured into the separator, which is made to revolve at such a rate that the two outgoing streams shall be equal. The separation of the fat is thus incomplete, and a large proportion of the watery solution passes out with it, the percentages of casein and of fat being in the original milk, say, 3.6 and 3.5, in the diluted 1.8 and 1.75, and in the cream and separated, or rather in the rich and poor milks, respectively 1.8 and 3.3 and 1.8 and 0.2, those in good nursing mother's milk being, according to Pfeiffer of Wiesbaden, 1.7 and 3.1. If, then, milk sugar be added in the proportion of 3.5 grammes to the litre the composition becomes identical with the very richest human milk. An incidental advantage accruing from the centrifugal rotation is that the rich milk is completely freed from the suspended particles of dung, dust, &c., which in virtue of their greater specific gravity gather round the sides of the drum, forming a scum, which is fatal to young pigs. These particles are the chief vehicles of the microbes which set up putrefactive

changes in a fluid which, though unstable, is absolutely germ-free and aseptic as it issues from the breast or udder, and to this difference many of the evils of artificial feeding are doubtless due. Gaertner's, if not actually sterile, is more easily sterilised than other milk.

THE HEALTH OF THE RT. HON. T. H. HUXLEY.

WE are glad to learn that Professor Huxley not only is holding his own, but that during the last two days there has been a steady, if slight, improvement. His condition is, of course, serious, as he is still suffering from the effects of influenza and bronchitis; but the strength is well maintained, the digestion better, and the appetite returning.

MEDICAL SOCIETIES AND HOMŒOPATHS.

THE West London Medico-Chirurgical Society has adopted the by-law quoted in our columns on the 13th inst. It has thus made it impossible for anyone practising so-called homœopathy to be nominated as a candidate for the membership of the society, and has also provided for the expulsion of any member who joins the ranks of homœopathy. The society is to be congratulated on having taken a step which propriety and harmony alike demand.

LONDON POST-GRADUATE COURSE.

THE summer term demonstrations and lectures will be given at Great Ormond-street, Queen-square, Moorfields, Blackfriars, Bethlem, London Throat, King's College Hospitals, and Cleveland-street Sick Asylum. The instruction will include Diseases of Children, of the Nervous System, of the Eye, of the Skin, of the Mind, of the Throat, Nose, and Larynx, &c., and Bacteriology. The fees are £1 1s. for eight lectures, and £2 2s. for sixteen. The term will commence on Monday, May 6th, and will end on Monday, July 1st. A prospectus can be obtained from the secretary, Dr. Fletcher Little, 32, Harley-street, London, W.

DIPHTHERIA IN LONDON.

IN the four weeks ended with last Saturday diphtheria has manifested some wide differences, both as regards amount and fatality, within the metropolis. Thus its weekly notifications have ranged between 130 and 170 and fatal attacks between 23 and 31, though the greatest deviation from the corrected average of deaths for any one of those weeks has been 5, and the mean of the averages and actual deaths for the whole period differs only by a unit—namely, average 27 and deaths 28. The total of deaths in the four-weekly period was 111, or just under half that of the similar period of 1894, in the several weeks of which the corrected average was exceeded by as many as 23, 30, 31, and 37 respectively. In the matter of notifications the current year shows for the period being treated a weekly average of less than 150, whereas that for 1894 yields upwards of 200; and in the matter of death-rate per cent. of cases 1895 gives just under 20, against 27 last year, the highest weekly mortality being in the present year 24, and in 1895 as much as 33 per cent. of notified cases. Comparison of the period in question with the four weeks of the present year immediately preceding does not leave a very favourable impression as regards attacks, as the 488 notified cases of the earlier period have been replaced by a total not far short of 20 per cent. in excess, and this, though the lesser total, is made up of sanitary district numbers, which were in seven instances upwards of 20, and ran as high as 46 in Greenwich and 57 in Camberwell. As showing the wide diffusion of the disease we may mention that in this same earlier period not one of the forty-three sanitary areas escaped invasion, though it is true that four had only a single notification each in the period. Thus,

we have at present an epidemic which is of smaller proportions than in 1894, though not showing signs of decrease as compared with earlier weeks of the current year, either in amount of disease or of death. Last week the admissions to hospital were 35, and the patients remaining under treatment 441, against 435 three weeks before. There were 15 deaths in Greater London, of which as many as 9 occurred in the West Ham district.

SIR JOHN BUCKNILL.

OUR contemporary the *Globe*, in its issue of the 19th inst., has a short paragraph respecting the visit of the Commander-in-Chief to Exeter on May 24th for the purpose of unveiling a statue erected by public subscription to commemorate the services rendered by Sir John Bucknill in connexion with the foundation of the Volunteer force. In congratulating Sir John Bucknill upon the fact that his memory is thus to be perpetuated, we cannot at the same time congratulate our contemporary upon its accuracy in heading the paragraph, "The late Sir John Bucknill." As far as our information goes he is "yet alive," and we trust that he may long have the opportunity of seeing with his own eyes the mark of honour erected to him in Exeter.

DEATHS UNDER ANÆSTHETICS.

A CHILD four years of age, weakly, rickety, and with unhealthy flabby tissues, recently became the subject of tonsillotomy at the Dudley Dispensary. The child was placed in an almost upright position on the porter's knee before an open window. Chloroform was then given from a folded towel; care was taken that free dilution with air was permitted, and two drachms in all were used. The child took the anæsthetic well, although it appears that the tonsils were very large and interfered with respiration. In from thirty seconds to two minutes breathing stopped and cyanosis came on. The child was placed on the floor and tracheotomy performed, but upon artificial respiration being practised normal breathing was resumed for a few seconds, and the child opened and closed his eyes. The heart then failed and death took place, micturition and defecation occurring. The necropsy showed enormous tonsils, glands which encircled and constricted the trachea at its bifurcation and the bronchi; slight catarrh and possibly slight narrowing of the windpipe existed. These notes are kindly supplied by Dr. E. Hawkins. The chloroform was analysed and found free from impurities. The difficulties of such cases are notorious, but we cannot help thinking it was ill-advised to increase the risks, as was done in this case, by placing the child in an almost upright posture. There is no doubt that if such children, flabby and weakly as they are, with an impaired respiratory passage and lowered vitality, are given an anæsthetic for tonsillotomy they should be carefully prepared, should have good, nourishing but easily assimilable liquid food two or even one hour before the operation, and if chloroform is given they should be placed in the recumbent position. A further death more or less connected with the anæsthetic has occurred in London. Mr. Atwood Thorne has kindly communicated the following particulars. The patient, a small, stout woman, who was in labour, was attended from St. Mary's Hospital. She had had seventeen previous confinements. When seen she was in a somewhat exhausted state, with a pulse-rate of 140; she had been in labour twenty-four hours. Mr. Thorne gave chloroform, and attempted to rotate the head digitally, as it was in the fourth vertex position; failing this the child was successfully delivered with forceps. Chloroform, which had been given for twenty minutes, was then stopped, three or four drachms having been used. Fifteen minutes later, when the woman was apparently coming out of

the anæsthetic quite naturally, she suddenly took a few deep breaths, became cyanosed, and respiration ceased. The tongue was protruding out of the mouth. The heart was still beating, and continued to do so for about ten minutes, but in spite of attempts made to restore the respiration it never recommenced. The necropsy, besides showing the usual "fatty degeneration of the heart," revealed no fact helping to explain why this woman died. The period at which the dyspnoea occurred and the cyanosis resemble cases of pulmonary embolism; but if this may be excluded it is possible that there was medullary hæmorrhage (which is known to have occurred under anæsthetics) involving the respiratory centre. Unfortunately the necropsy was not made for ninety hours, so that much of the value of the investigation is, from the point of view of science, wholly lost.

THE PREVENTION OF OVERLAYING.

It is a simple matter to expose and condemn the practice which is mainly accountable for the overlaying of infant children. Neither is there any difficulty in prescribing the only possible preventive of this so-called accident. A box, a basket—in short, any one of twenty simple contrivances—might form an extemporised crib in cases where a cradle or cot-bed is not obtainable. Consequently, there is no excuse for the too often fatal custom which allows an infant to sleep with its parents. Unfortunately, it is only too easy to let ill alone and to do nothing by way of precaution. The careless, the indolent, and the drunken (it is notorious that the great majority of cases of overlaying have occurred on Saturday night¹) continue to neglect even such an elementary safeguard as that we have mentioned. The obvious result, as we learn from a statement recently made by Mr. C. L. Drew, is that from 600 to 800 inquests are annually held in London alone upon overlain children. There is a natural reluctance to invoke the aid of legislation in restraint of every fault in domestic management, but it must be evident that we have here sufficient justification for such assistance. The case is, indeed, one which very strongly suggests the necessity of increased popular instruction in this subject by means of the Press and every other available channel. We are clearly of opinion, however, that some deterrent is also called for, such, for example, as the imposition of a reasonably heavy fine in all cases where the precaution of using a separate bed of some sort for children has been overlooked.

THE PATHOLOGY OF THOMSEN'S DISEASE.

It is barely twenty years since there was described in the *Archiv für Psychiatrie* an affection characterised by singular muscular phenomena in several members of one family. The affection, since known by the name of the physician who then first described it, has been studied by many observers, amongst whom may be especially mentioned Professor Erb, who termed the condition "myotonia congenita." The main features of the affection, apart from its hereditary character, consist in an increased volume of muscular masses, suggestive of a kinship to pseudo-hypertrophic paralysis, accompanied by notable impairment of power, and the assumption of a state of tonic spasm on the contraction of the affected muscles. There is, further, an increased excitability to faradism and galvanism, with a tendency to the reaction of degeneration. Moreover, Professor Erb found that ensuing on the "closure contraction" of galvanism there occurred a series of slow and regular undulatory contractions, which gradually spread from the negative to the positive pole, a phenomenon which he termed the "myotonic reaction." Hitherto no opportunity has occurred for full observation of the morbid anatomy of

Thomsen's disease, but a paper in the *Revue de Médecine* for March by Dr. Déjérine and Dr. Sottas supplies this deficiency. It is founded upon the case of a man who first came under observation at the age of thirty-two, having since infancy suffered from this affection. It was characterised in him by marked hypertrophy of the muscles of the lower limbs and trunk, and less obvious change in those of the upper limbs. All the muscles of the body were rigid when in contraction, and were but slowly relaxed; the myotonic reaction was present. The patient succumbed at the age of thirty-seven from acute nephritis. No change was found in the nervous system, central or peripheral, but an examination of the muscular system, specimens being taken from all parts, afforded an insight into the nature and progress of the lesions therein. These lesions consisted, in the first place, in a nuclear overgrowth, following which the muscular substance proper apparently becomes swollen, the fibrinæ becoming fused together, whilst the transverse striation is retained or is even more pronounced than normal. Measurement showed a notable increase in the diameter of the affected fibres. There is, further, a like increase in the interfibrillar protoplasm, rendering the "Cohnheim's fields" more distinct. In more advanced stages the muscular substance disintegrates, and vacuolar spaces are formed in and between the fibres. It is remarkable that the connective tissue does not undergo any hyperplasia, nor is there any excess of adipose tissue as in pseudo-hypertrophic paralysis. It may be remarked that the changes described in this paper agree in the main with those found by others who have examined fragments of the hypertrophied muscles excised during life; but the record of Dr. Déjérine and Dr. Sottas is far more complete, since they had the opportunity of tracing the changes from early to advanced stages. It is pointed out that the hypertrophy commences and is most marked in those muscles which are the most exercised, and it is concluded that in Thomsen's disease we have to do with a "hypertrophy of functional origin." The affection thus ranks with the group of dystrophies of the muscular system known as primary myopathies.

THE RELIEF OF CHITRAL.

NOTHING more exciting has taken place for some time than the race between the forces to win the honour and glory of relieving Surgeon-Major Robertson and his beleaguered companions in Chitral. The display of pluck and energy, and the exhibition of splendid audacity, alternating with periods of suspense and doubt during the absence of news, have imparted a dramatic force to the military incidents as they have unfolded themselves from day to day. The fact, too, that the exhibition of daring and endurance was most conspicuous on the part of the smaller and weaker force touched the public sentiment and caused the brilliant and remarkable march of Kelly's force to be followed with great sympathetic interest. The fortitude and manly qualities brought out in this expedition have made people feel that so long as these endure the interests of this country are safe, and that, whatever the emergency, there would always be men ready to do their "level best." The lads that go out as officers to India and elsewhere leave England with the corners of the British flag grasped unconsciously in their hands and spread it over the four quarters of the globe. And not only have the pluck and endurance of the officers and men of the British army been fully exemplified, but the splendid qualities of the native army of India have been emphasised on this occasion. Defying climate and disease, labouring and fighting under a tropical sun or amidst icebergs with the same indomitable perseverance, scornful of difficulty and defeat, the forces have pursued their way. The marches that have been made, the mountain passes that have been crossed—the height of the Shandur Pass is

¹ Vide THE LANCET, Aug. 20th, 1892.

12,000 ft. above the sea level—and the physical obstacles that have been surmounted by the different columns taking part in this expedition will cause the relief of Chitral to occupy a memorable place in military history. Spite of floundering in snow, crossing ice-fields, and encountering storms, and in face of extreme difficulties in the transport of the necessary war material and food, the men, one and all, native and European, have apparently gone ahead, fighting with nature and man, with undaunted spirits and excellent health. The medical history of the expedition, when it comes to be written, will, if less exciting, be as interesting as its military history.

MR. PASSMORE EDWARDS AS A HOSPITAL PATRON.

MR. PASSMORE EDWARDS must be a many-sided man. He is the reputed proprietor of papers which traduce medical research and whose columns are open to every faddist who will decry the methods by which, and the men by whom, medical science is established. But he is always ready to open a hospital, or even take part in the proceedings of a medical school, and to put down a substantial sum for providing poor people with the very medical service that is decried in his papers. It is not for us, perhaps, to do more than look with awe, if not with admiration, on a gentleman whose sense of duty enables him to play such diverse parts. The last act of this good man's life was to open a new wing of West Ham Hospital, the cost of which he is defraying. By this act of beneficence Mr. Passmore Edwards supplies twenty-four new beds, in which patients will receive all the benefits of medicine that accrue from the studies and the researches so severely and suspiciously regarded in Mr. Passmore Edwards' papers. We can only take note of the fact, and conclude that deeds are more than words, that Mr. Edwards, after all, has a high opinion of medicine and of those who practise it, and that when he allows his papers to be the medium of contrary opinions he is so conscious of their absurdity as to believe that they will not be acted on.

SOLAR OBSERVATIONS WITH THE UNPROTECTED EYE.

Dr. GEORGE MACKAY of the Royal Infirmary, Edinburgh, has done good service in pointing out the dangers of observing eclipses and solar phenomena with the naked eye in a pamphlet he has written on this subject and in the *Ophthalmic Review*. He cites the case of Galileo, who is said to have lost his vision in this manner. Sir Isaac Newton was equally imprudent, and permanently damaged his retina by looking at the sun for a moment through a telescope. He, in fact, narrowly escaped complete loss of central vision, for he long suffered from a scotoma, or central darkness, and although he partially recovered from this condition, it was only necessary for him to think of the lesion to cause an image of the sun's disc to rise before him. Dr. Reid, the Professor of Moral Philosophy at Glasgow, was also a sufferer, and when he observed the passage of Venus in May, 1761, took no precaution to diminish the brilliancy of the light, the result being that all the objects he looked at appeared to be deformed. In this case there was probably in the first instance some subretinal effusion and the retina did not perfectly reapply itself to the choroid. Dr. Mackay has met with no less than seventeen cases of persons in whom the vision was impaired as the result of the investigation with the unprotected eye of the eclipses of 1890 and 1891. Still more recently Dr. James Barrett of Melbourne has reported a case in which an eclipse of the sun was watched for a quarter of an hour by a girl aged seventeen; but in this case some precautions were used, as she protected her eyes with coloured glasses, two of which were blue and the other two red and yellow respectively. A haze

or central misty spot was noticed in the course of a fortnight, which remained unaltered after the lapse of three months. It is obvious that no inspection of sun spots or other solar phenomena should be made with an ordinary telescope under any circumstances, and that great circumspection should be used in watching the phenomena, even through coloured glasses. Probably all trouble could be averted by looking at the image of the sun as reflected from a fragment of blackened glass.

THE University of Glasgow has just conferred the degree of LL.D. *in absentia* on Surgeon-Major Laurence Augustine Waddell, who graduated at Glasgow in 1878 as M.B. and C.M. (with honours), entered the Indian Medical Service, and while stationed in Calcutta wrote several papers on the pharmacology of Indian medicinal products. He also made a collection of Sikhim birds, which he fully described and afterwards presented to Dr. William Hunter's Museum in Glasgow University. He is, moreover, an adventurous traveller, being one of the few who have penetrated into the territory of the Grand Lama of Thibet and studied the religious system of that country. He has recently published a work entitled "The Buddhism of Thibet or Lamalism." Surgeon-Major Waddell was for some time editor of the *Calcutta Medical Journal*.

A CONFERENCE on sanitary progress and reform was opened at Manchester, on the 24th inst., in the presence of a large number of representatives from all parts of the country. The inaugural address was delivered by Dr. Simpson, who referred to the great strides made of late years in matters relating to sanitation in its various branches. The proceedings extend over three days. We hope to print Dr. Simpson's address next week in full.

THE annual conversazione of the Royal Society will be held on Wednesday, May 1st.

THE REPORT OF THE ROYAL COMMISSION ON TUBERCULOSIS.

THE report of the Royal Commission on Tuberculosis was presented to Parliament on the 22nd inst. As appointed on Nov. 14th, 1894, it consisted of Sir George Buchanan (chairman), Professor Browne, Dr. J. F. Payne, and Professor Burdon Sanderson, and the report receives the assent of all its members.¹ This Commission succeeded to the Royal Commission of 1890 on the death of the chairman, Lord Basing, and its report is based upon evidence received and inquiries originally instituted by the original Commission. Mr. Leopold Hudson, F.R.C.S., has throughout acted as secretary. The terms of the reference made to the Commission were: "To inquire and report what is the effect, if any, of food derived from tuberculous animals upon human health, and, if prejudicial, what are the circumstances and conditions with regard to tuberculosis in the animal which produce that effect upon man."

Lines of Enquiry.—It appears that the Commission, after examining a number of distinguished pathologists and physicians and making inquiries by letter among medical officers of health and others, came to the conclusion that they had not sufficiently definite evidence on the matter referred to them. Accordingly, they instituted inquiries—(1) by Professor McFadyean into the means of recognising the tuberculosis in animals during life; (2) by Dr. Sidney Martin, as to the influence upon lower animals of food of tuberculous origin; and (3) by Dr. Sims Woodhead, as to the effects of cooking processes upon food from tuberculous animals; and

¹ A memorandum by Professor Browne concerning the effect of the Commission's investigations upon food salesmen is appended to the report.

it is upon the results of these investigations that the report is chiefly based.

Influence upon animals of food of tuberculous origin; influence upon man.—Briefly dismissing as unsatisfactory any direct evidence of the effect of food of tuberculous origin upon man, the Commission relies upon the experiments conducted for it on lower animals, and these show, then, firstly, that uncooked food (meat or milk) derived from tuberculous animals, whether consumed by rabbits, guinea-pigs, cats, or pigs, produces tuberculosis in a considerable proportion of each; secondly, that tuberculous matter added if only on one occasion to the ordinary food of any of these animals causes a still larger proportion to become tuberculous. The facts and figures about these animals, together with an account of necessary control experiments, are given, and they prove to the Commission that tuberculous matter exists in ordinary food derived from a tuberculous animal, and that when this food is consumed by lower animals it is capable of producing tuberculosis among them. Following this is Section 22 of the report: "We cannot refuse to apply, and we do not hesitate to apply, to the case of the human subject the evidence thus obtained from a variety of animals that differ widely in their habits of feeding—herbivora, carnivora, and omnivora. As regards man, we must believe—and here we find ourselves agreeing with the majority of those who gave evidence before us—that any person who takes tuberculous matter into the body as food incurs some risk of acquiring tuberculous disease." Next, after stating explicitly that tuberculosis is to be regarded as the same disease in man and in food animals, the report considers the nature of human tuberculosis liable to originate in food. It will be observed that the Commission takes the view that no distinction is to be drawn in nature between tuberculous diseases originating in food infection and those originating in other ways. They point, however, to the probability that the greatest effect of food infection is to be found in the tuberculous intestinal lesions of children.

Prevalence of tuberculosis in food animals. Recognition of it.—The knowledge which the Commission has been able to obtain of the prevalence of tuberculosis among animals brought for slaughter in the United Kingdom appears to have been but small, seeing that in none of our public abattoirs is systematic inspection made for tuberculosis with anything like the precision employed in many places on the Continent. Accordingly, we find the report quotes from the records of slaughter-houses both in Berlin and Copenhagen, having reason to believe that they present a broad resemblance to the conditions of tuberculosis among animals brought for slaughter in this country; and such statistics as are available for the United Kingdom confirm them in this view. The percentages of animals found to be tuberculous in Copenhagen (1890-93) and Berlin (1892-93) respectively were: oxen and cows, 17.7 and 15.1; swine, 15.3 and 1.5; calves, 0.2 and 0.23; sheep, 0.0003 and 0.003. Attention is drawn to the greater prevalence among cows than oxen, and among both as compared with calves. The rest of the report deals chiefly with food from cattle. Of diagnosis of tuberculosis during life the Commissioners speak very guardedly. The literature of the subject and the results of Professor McFadyean's special inquiry convinces them that extensive tuberculous disease may exist in cattle that appear to all clinical tests to be in perfectly good health. And they are clearly indisposed to believe that a completely trustworthy test of the presence of tuberculosis has yet been proved to exist in the reaction to tuberculin. "Professor McFadyean finds, in his own hands, that this test substance has frequently led to erroneous inferences. He records, as the total outcome of his experiments, that he received wrong indications from tuberculin about the presence or absence of tubercle in cattle in the case of twenty-four animals out of seventy-five; nevertheless, he sums up his report by the statement: 'I have no hesitation in saying that, taking full account of its imperfections, tuberculin is the most valuable means of diagnosis in tuberculosis that we possess.' And we understand that, since the time of Professor McFadyean's experiments, the method of using tuberculin as a test has been much improved, and that it is now regarded as affording more trustworthy indications for diagnosis."

Circumstances determining danger to man from meat and milk of tuberculous origin. (a) *Danger from meat.*—The circumstances of danger from meat are next discussed in several pages of the report, and the conclusions of the Commission, chiefly based on Dr. Martin's experiments, are set forth in a closely reasoned argument which is difficult to

summarise. Tuberculosis of the animal is chiefly a disease of organs which are for the most part removed in the process of dressing. Some organs, however, may be left in the dressed carcass, although "to a practised eye it is hardly possible that tuberculous matter in these organs can escape detection." Apart from such tuberculous masses, the material of tubercle, even in advanced cases, is not often found in the ordinary butcher's joint, certainly very rarely in muscle substance, although small tuberculous lymphatic glands may occasionally be found, for instance, in the intermuscular fat. "Yet there is always a difficulty in making sure of the absence of tuberculous matter in any part of a carcass that shows evidence of tubercle elsewhere." The report now considers the results of Dr. Martin's experiments with the substance of meat prepared in the ordinary way from tuberculous animals, but taken free from any obvious tuberculous mass. In these experiments he tested the infective quality both by inoculation of portions of the meat into test animals and by giving it to other test animals as food. In the meat substance of twenty-one tuberculous cows (cows were found the most convenient animals in these researches) he "could not get visible evidence of tubercle except in two instances, and there it was of very small amount. He records the results of his other tests as follows: 'Of eight cows (mild tuberculosis) the meat of one gave positive results in one animal from inoculation; none by feeding. Of eight cows (moderate tuberculosis) the meat of three gave positive results in four animals from inoculation; none by feeding. Of five cows (generalised tuberculosis) four gave positive results either by inoculation or by feeding, one only out of the four appearing to answer to both tests.' The animals which had yielded affirmative results to his test of minute examination were not among the last five; they were in the group of cows with 'moderate tuberculosis,' and had given no result by feeding test animals with meat from their carcasses, though meat from one of the two had, upon inoculation, responded to the test."

These results were thus completely out of accord with the determinations Dr. Martin had made of the presence or absence of demonstrable tubercle in each case. And in an able argument the Commissioners explain the views he took of his results—namely, that the power of infection of meat from these carcasses is mainly due, not to tuberculous matter left in the meat *in situ*, but to matter carried from tuberculous organs in the process of dressing by the butchers' knives or cloths and thus smeared freely over the carcass. It is obvious that the danger of such a proceeding must increase *pari passu* with the amount and distribution of the tuberculosis in the animal. While accepting this as the chief danger of the meat, however, the report observes that "To have demonstrated this extrinsic way of rendering dangerous the meat substance of tuberculous animals is to destroy all evidence that might otherwise have been attained respecting the wholesomeness or unwholesomeness of the proper meat substance towards Dr. Martin's test animals." The report continues with this observation: "We note in passing that this method of endangering the meat substance could not have been detected upon carcasses from which the organs, together with any 'grapy' deposit, had been removed; and it is pertinent to observe, in connexion with a contamination so effected, that this extrinsic danger to harmless meat (or to meat that was, for all that is shown to the contrary, harmless) might just as well be encountered by meat from another animal (whether pig, sheep, or calf, or cow) that was perfectly free from tubercle, but only had happened to be the next animal brought to the same slaughterer." Upon the bearing of the conclusions so arrived at the Commissioners state that they are prepared to believe, with Dr. Martin, that if sufficient discrimination and care were exercised in taking meat from tuberculous cattle a great deal of meat from them might, without danger, be consumed by the community; and they point to the practice of public abattoirs on the Continent as being founded on the same belief.

They proceed to summarise the precautions that Dr. Martin advises: "He would advocate, as a principle, that the operations of slaughter and dressing should be done under skilled supervision, with the object of securing the removal and destruction of every part of a carcass that contained any tubercle whatever, and also the destruction of the whole carcass in cases where the animal was found to have

* Section 104, p. 31.

advanced or generalised tuberculosis. He indicates, for the assistance of any meat inspector, various evidences of the disease having reached that more serious stage. For the rest, Dr. Martin sees no objection to the sale of meat-substance from carcasses which have shown only localised tuberculosis, and from which every particle of tubercle has been skilfully removed; provided always that, in every subsequent process of preparing the meat for sale, due care be taken to guard the saleable portions from contamination by tuberculous matter." The Commissioners state their opinion that these suggestions are based on well-ascertained pathological facts, and that the supervision recommended would tend in an important measure to the security of the public. Yet they show their appreciation of the difficulties of obtaining this security for all meat, especially for imported meat when the conditions under which the carcass was prepared cannot be ascertained. "It is hardly necessary to point out that little evidence about the more serious degrees of tuberculosis in the animal would be discoverable in carcasses from which the organs had been removed, and that this is habitually the case with so-called 'dead meat,' whether English or foreign. Still, there are indications in such a carcass, to the eye of an experienced inspector, of the more dangerous forms of tuberculosis having existed in the animal."

(b) *Circumstances determining danger from milk.*—Upon this matter the report is able to be much more definite and to adduce striking evidence (based upon differential experiments made by Dr. Martin) to show that the milk of a tuberculous cow is only infective when it comes from a tuberculous udder. The Commissioners set forth their experiments, which seem conclusive. They point out that the udder affection is not peculiar to the advanced stage of tuberculosis, but that it may occur in slighter cases. They also draw attention to the great virulence of milk from this source, and point to the fact that the mixed milk from all four teats of a cow with tuberculosis of one quarter of the udder only proved to be every whit as infectious as milk from the tuberculous quarter alone. Further, butter, skimmed milk, and buttermilk from a cow with a tuberculous udder are actively infectious. In Section 62 the rapidity with which tuberculosis may attack the udder is noted, and an observation of Dr. Woodhead is quoted in which he says that on several occasions he has found tuberculosis of the udder developed during the interval of a fortnightly inspection of cows. The Commission comes, therefore, to the conclusion: "The withdrawal from dairies of every cow that had any disease whatever of her udder would form some approach to security against the serious danger incurred by man from the use of tuberculous milk, but it would not be an adequate security. The presence in a dairy of a tuberculous cow, as Drs. Martin and Woodhead have shown, is a decided source of danger to the public, especially having regard to what we have learnt respecting the rapid development of tuberculosis in the udder, and the degree of danger to milk consumers incurred by the invasion of the udder in tuberculous cows. It follows from the observations here recorded that it is of supreme importance to the consumers of milk that the existence of any tuberculous disease of the udder should be ascertained without delay. Now there is no difficulty whatever about recognising the presence of some abnormal condition in a cow's udder, and the presence of such condition, whatever it be, demands that the judgment of a responsible expert should forthwith be obtained about its nature, unless, indeed, the owner prefers to slaughter the cow without delay. If the expert finds tubercle bacilli in the milk the cow has dangerous tuberculosis of the udder. If he does not find them he may apply the further test of inoculating some susceptible animals with the milk, and thereby learn the nature of the udder disease. By this test he will very rarely be misled. Obviously the cow must be in seclusion, and every particle of her milk must be treated as highly dangerous, during any delay that can be permitted for diagnostic purposes, and until the disease has been proved not to be tuberculosis."

Influence of cooking upon tuberculous meat and milk.—As a result of Dr. Sims Woodhead's experimental researches the Commission reports that while in ordinary cooking the temperature on the surface of the joint is sufficient to destroy the infective quality of tuberculous matter in that situation, yet cooking, no matter by what method, cannot be relied upon to sterilise such matter below the surface. Particular attention is drawn to Dr. Woodhead's remarks upon "rolled" meat, which is specially likely to contain in its interior either tuberculous serous membrane or tuberculous

matter originally smeared on the surface in the preparation of the slices into rolls. Agreeing with Dr. Woodhead's observations, the report expresses the belief that no ordinary cooking would destroy infective material in such rolls, and that these, in point of fact, "probably form the maximum of danger to meat consumers." In order to destroy the infectiveness of tuberculous milk the Commission warmly advocates boiling, and evidently regards with suspicion any advice to the public to attempt to sterilise milk by heating it to a temperature short of boiling point.

The following is the recapitulation appended to the report.

RECAPITULATION.

"We have obtained ample evidence that food derived from tuberculous animals can produce tuberculosis in healthy animals. The proportion of animals contracting tuberculosis after experimental use of such food is different in one and another class of animals; both carnivora and herbivora are susceptible, and the proportion is high in pigs. In the absence of direct experiments on human subjects we infer that man also can acquire tuberculosis by feeding upon materials derived from tuberculous food animals. The actual amount of tuberculous disease among certain classes of food animals is so large as to afford to man frequent occasions for contracting tuberculous disease through his food. As to the proportion of tuberculosis acquired by man through his food or through other means we can form no definite opinion, but we think it probable that an appreciable part of the tuberculosis that affects man is obtained through his food. The circumstances and conditions with regard to the tuberculosis in the food animal which lead to the production of tuberculosis in man are, ultimately, the presence of active tuberculous matter in the food taken from the animal and consumed by the man in a raw or insufficiently cooked state. Tuberculous disease is observed most frequently in cattle and in swine. It is found far more frequently in cattle (full grown) than in calves, and with much greater frequency in cows kept in town cow-houses than in cattle bred for the express purpose of slaughter. Tuberculous matter is but seldom found in the meat substance of the carcass; it is principally found in the organs, membranes, and glands. There is reason to believe that tuberculous matter, when present in meat sold to the public, is more commonly due to the contamination of the surface of the meat with material derived from other diseased parts than to disease of the meat itself. The same matter is found in the milk of cows when the udder has become invaded by tuberculous disease, and seldom or never when the udder is not diseased. Tuberculous matter in milk is exceptionally active in its operation upon animals fed either with the milk or with dairy produce derived from it. No doubt the largest part of the tuberculosis which man obtains through his food is by means of milk containing tuberculous matter. The recognition of tuberculous disease during the life of an animal is not wholly unattended with difficulty. Happily, however, it can in most cases be detected with certainty in the udders of milch cows. Provided every part that is the seat of tuberculous matter be avoided and destroyed, and provided care be taken to save from contamination by such matter the actual meat substance of a tuberculous animal, a great deal of meat from animals affected by tuberculosis may be eaten without risk to the consumer. Ordinary processes of cooking applied to meat which has got contaminated on its surface are probably sufficient to destroy the harmful quality. They would not avail to render wholesome any piece of meat that contained tuberculous matter in its deeper parts. In regard to milk we are aware of the preference by English people for drinking cows' milk raw—a practice attended by danger on account of possible contamination by pathogenic organisms. The boiling of milk, even for a moment, would probably be sufficient to remove the very dangerous quality of tuberculous milk. We note that Your Majesty's gracious commands do not extend to inquiry or report on administrative procedures available for reducing the amount of tuberculous material in the food supplied by animals to man, and we have regarded such questions as being beyond our province."

THE SURGICAL CONGRESS IN BERLIN.

(FROM OUR BERLIN CORRESPONDENT)

FIRST SITTING, ON APRIL 17TH.

THIS Congress was opened in the great hall of the Langenbeck House under the presidency of Professor Gussenbauer (Vienna). After the introductory proceedings the President mentioned that American surgeons propose to hold international surgical congresses at regular intervals and ask this meeting to approve of their intention. The Congress was of opinion that a more detailed programme ought to be brought before it, and authorised the President to take the necessary steps to this end.

Cerebral Surgery.

Professor von Bergmann (Berlin) read a paper on the Progress of Cerebral Surgery. He said that although increased knowledge of the physiology and pathology of the brain had enabled surgeons to deal with cerebral diseases much circumspection was necessary in this branch of surgery. The procedure in operations on the brain is now quite different from what it formerly was. Instead of the chisel and the trephine we now use a circular saw driven by an electric engine, which works with speed and certainty and can easily

be stopped. He would not to-day speak on the subject of tumours, but only on the other indications for operative interference. In 1889 he had suggested that Jacksonian epilepsy might be influenced for the better by trephining, but he now wished to modify this opinion, as he had found only those cases benefited where a cyst or some other palpable cause of the disease was present. Cerebral abscess must always be operated on. Its diagnosis is easy if the etiology is considered. The principal cause of cerebral abscess is inflammation of the middle ear; it is usually situated in the temporal lobe. The operation in those cases should commence with the tegmen tympani. A decided advance is the operation for suppurative thrombosis of the sinus, which, of course, often follows suppuration within the mastoid process. The sinus can be arrived at from the tegmen tympani. In the first place, an exploratory puncture is made, and if it yields pus the opening must be enlarged and filled with iodoform gauze. In cases of increased cerebral pressure trephining is to be performed also, the effect of the puncture lasting for only a short time. The puncture of the spinal canal in the lumbar region suggested by Professor Fürbringer, and mentioned in the last number of THE LANCET, Professor Bargmann believed to be of great diagnostic value.

Dr. Ledderhose (Strasbourg) had seen a case of cerebral injury where paralysis of the limbs was on the same side as the lesion of the brain. Several cases of this kind have been reported in surgical literature, and are caused by congenital abnormalities in the decussation of the cerebral fibres.

Dr. Eiselsberg (Vienna) described the methods of closing apertures in the skull. These apertures, he said, may arise from three causes—traumatic lesions, the effects of zymotic diseases, and neoplasms. They can be dealt with in two ways: by König's method, which consists in covering them with periosteal flaps; or by that of Kraenkel, who uses plates of celluloid. In one case after the implantation of the celluloid an epileptiform convulsion ensued, so that he was compelled to remove the celluloid and then found a large hæmatoma beneath it. He therefore advises the performance of two separate operations.

Dr. Fraenkel (Vienna) claimed as an advantage of the celluloid implantation that it prevents adhesions of the dura mater, which sometimes happen in cases where König's operation is performed.

Dr. Czerny (Heidelberg) said that he had not been so fortunate as others in applying celluloid plates. He recommended the implantation of pieces of the tibia.

The Surgical Treatment of Graves' Disease by Extirpation of the Thyroid Gland.

Professor Mikulicz (Breslau) discussed the Surgical Treatment of Graves' Disease by Extirpation of the Thyroid Gland. He has performed this operation several times with good results. The nervous symptoms very soon disappeared after the operation, and the general state of the patient became better. The next effects are decrease of the cardiac trouble, and ultimately of the exophthalmos. As a proof of the good effect of the operation, Professor Mikulicz asserted that he had never seen patients so grateful as those who had been operated on. He does not believe that the operation only acts by means of suggestion. He is of opinion that Graves' disease must be regarded as a toxic process originating in the thyroid gland.

Professor Kocher (Berne) reported that in the last 900 cases operated on by him the method of total extirpation was wholly abandoned, and only the partial operation was performed. Since proceeding in this way he has not had any cases of cachexia strumipriva except in one instance, where the remaining part of the gland was found to be atrophied. This case was cured by the internal administration of thyroid gland. Although he was well satisfied with his results, the mortality being only 12 per cent., he hoped that the number of operations would soon be reduced, and that internal medication would be substituted. He made a very remarkable communication, describing the influence of the internal administration of thyroid extract and phosphate of potassium, and showed several photographs of patients where the reduction of the gland after the use of these internal remedies was very obvious. His address was listened to with much interest, and caused a great sensation.

Professor Mikulicz said that the internal use of thymus gland was also able to reduce the goitre.

Professor von Eiselsberg (Utrecht) had not found this to be the fact in his experience.

Dr. Schuchardt (Stettin) showed a case in which sup-

purating peritonitis, caused by a perforating ulcer of the stomach, had been successfully treated by operation.

SECOND SITTING, ON APRIL 18TH.

The Etiology of Movable Kidney.

Professor Küster (Marburg) discussed the Etiology of Movable Kidney. He was of opinion that this condition always arises from mechanical causes. During respiratory action, especially in women who wear tightly laced corsets, and whose abdominal walls have become thin by reason of repeated pregnancy, the ribs exercise a pressure which in course of time loosens the kidney. Direct violence, such as a fall or a blow, may also be the cause of the displacement. Rupture of the kidney in men and movable kidney in women arise often from the same cause. It is remarkable that 93 per cent. of the total cases of rupture of the kidney happen in men and only 7 per cent. in women, whereas 93 per cent. of the cases of movable kidney occur in women and only 7 per cent. in men.

Dr. Lindrer (Berlin) said that mechanical causes alone were not sufficient to explain these cases; traumatic lesions produce movable kidney only when a congenital disposition exists. The lengthening of the renal vessels proves that the cases are congenital.

Dr. Küster replied that this lengthening of the renal vessels is only found in patients who have for a long time been the subjects of this condition, and that it must accordingly be regarded as a consequence and not as a cause of the abnormality.

Dr. Kölliker (Leipzig) reported a case where after a severe injury (a boy had been thrown into the air by four others and had fallen on his lumbar region) a rupture of the kidney was produced. The wound was enlarged and filled with iodoform gauze, thereby avoiding the necessity for extirpation. The boy completely recovered, and his urine is at present normal.

A Series of Operations on the Stomach.

Professor Mikulicz reported 103 Operations on the Stomach with 23 deaths. It was remarkable that 13 deaths in 35 patients happened during the first ten years, whilst in the last three years and a half out of 68 patients 10 only died. This fact proves that the results are rendered more and more satisfactory by the improvements in surgical methods and by the increasing dexterity of the surgeon. The non-success of operations for carcinoma depends on the weakness of the patient. To improve their general state he uses subcutaneous injections of saline solutions. When the practicability of an operation is doubtful he recommends the making of a very short abdominal incision from 2 to 4 centimetres in length (= from $\frac{1}{2}$ to $1\frac{1}{2}$ in.), so that one finger may be introduced and the abdominal organs explored. If an operation is inadvisable the small wound can easily be closed by sutures and the patients need not be confined to bed. After gastro-enterostomy the patients lived on an average for six months, but after resection for a year and a half. He accordingly prefers the latter operation, those cases of course excepted where the lymphatic glands and the peritoneum are attacked. The operative procedures, Professor Mikulicz said, could scarcely be improved, but an earlier diagnosis might be the means of saving many cases.

Dr. von Eiselsberg recommended the excision of the growth and the closing of the ends both of the stomach and of the duodenum by sutures. This done, a regular gastro-enterostomy follows, and the chyme easily passes through the new aperture.

Dr. Doyen (Rheims) said that the pain in nearly all painful diseases of the stomach is localised in the pylorus. Dilatation of the stomach arises, in the absence of any mechanical cause, from spasmodic contractions of the pylorus. Seven patients who suffered from severe dyspepsia and fourteen who were the subject of gastric ulcer without stenosis were completely cured by gastro-enterostomy.

Dr. Fischer (Strasbourg) said that in gastrostomy a secure union of the stomach with the abdominal walls may be difficult. In such cases he recommended that the stomach should not be opened, but that the patient should be fed by a cannula similar to Pravaz's, but of course much larger. He pushes the cannula through the walls of the stomach lying in the abdominal wound and injects a quantity of fluid food, milk, &c. In course of time the opening in the stomach is enlarged and a fistula is formed.

Intestinal Invagination.

Dr. Rydygier (Cracow) discussed Intestinal Invagination.

The cases are usually treated too long by internal remedies, and accordingly come too late to a surgeon. The mortality is, therefore, very high (75 per cent.), especially in acute cases. The treatment in both the acute and the chronic form should consist in immediate laparotomy. Disinvasion should always be tried; if it does not succeed resection of the intestines becomes necessary. He has had twelve cases, of which three were successful, whilst according to former statistics none of the patients recovered. Enterostomostomy and the formation of an artificial anus should never be attempted, the result of these operations always being rapid irritation.

(To be continued.)

THE REPORT OF THE ROYAL COMMISSION ON OPIUM.

THE Royal Commission appointed in June, 1893, to inquire into the question of the Indian traffic in opium was admittedly composed of men eminently qualified to conduct such an investigation, and they have, after an unusually protracted and exhaustive inquiry, at length made their report. The result can only be described as a crushing blow to the anti-opium faddists. A very large amount of evidence was taken, of such variety, strength, and character as to leave no doubt on the subject. There was a marked preponderance of testimony in favour of the view that the common use of opium in India is a moderate use leading to no evident ill-effects, and that excess is exceptional and condemned by public opinion. Such is the gist of the report which, with one dissentient (Mr. H. J. Wilson, M.P.), was signed the members (nine in number) of the Commission. The truth is that however well meaning the anti-opium party in this country may be their statements, when brought to the test of facts and impartial inquiry, have been shown to have been either ridiculously exaggerated or even altogether unfounded. We must take human nature as it is, as it exists all the world over irrespectively of the colour of the skin, and nowhere do we find that men and women regulate their life and customs by some abstract rule of perfection, for the very simple and sufficient reason that they cannot. The needs and requirements of life, its burdens as well as its joys, the hunger, fatigue, weariness, sickness, or *ennui* that falls to the lot of so many, have to be taken into account as well as its sources and seasons of joyfulness and exhilaration. In a large measure the conditions of our lot in life mould us into what we are, and everywhere give rise to a craving of some sort or other for such things as will exhilarate or soothe us and, if even temporarily and delusively, bring us into harmony with an environment out of which we cannot escape. But are we in a position in this matter to cast a first stone at Eastern nations? If we reverse the situation and suppose that the natives of India had sent a commission to this country to inquire into the drink question—into the sum spent per head by our population on alcohol, and the degradation, misery, and crime which are too often the outcome of it all—can there be any reasonable doubt that the evils traceable to alcohol here would appear to such a commission enormous, and those arising from the abuse of opium there, in India, altogether insignificant in comparison with them. No doubt the inordinate use of opium is a great evil, but so far that matter is an inordinate consumption of tea or tobacco. But the use of opium, if common enough in the populations of India, is nevertheless a moderate use and has not been shown to be by any means harmful—rather the reverse considering the conditions to which the people are exposed and under which they have to live. The medical and expert evidence brought before the Commissioners convinced them that the use of the drug was not harmful, and witnesses from every part of India testified to the belief in opium as the common domestic medicine of the people, and that it was commonly had recourse to by the rural population in malarious and damp districts as a prophylactic against fever and for the relief of diarrhoea, rheumatism, and other complaints. Quite apart from the merits of this belief the Commission considers that its existence has been conclusively established by such a mass of evidence and observation as to represent public opinion on the subject. In fact, the Commission which many

hoped had gone out to curse the existing system has ended by blessing it altogether. Opium is, under certain circumstances, a sort of diet to many of the poorest classes in India—and the poorest are extremely poor there; it economises the fuel and eases, as it were, the animal machine of the hard-working coolie in times when the demands upon his muscular and nervous energies are great and his food-supplies small. The Mussulman troops take their dose of opium with far less injury to themselves than the navy takes his beer or the miner in the Peruvian Andes consumes his coca leaf. A prohibition of the growth of the poppy and the manufacture of opium in British India, the Commission declares, has not been shown to be necessary or to be demanded by the people; and as regards its prohibition in the protected States it could only be effected by an arbitrary exercise of power which would probably be resisted by the native rulers and their people; in brief, the prohibition of opium would be strongly opposed by the great mass of the population of India and a source of financial embarrassment to its Government. The report is a long one, and there is also a memorandum appended to it by Sir J. B. Lyall on the historical part of the question in India and China, and a very able paper by Sir W. Roberts dealing more especially with the medical aspect of the question.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6407 births and 4127 deaths were registered during the week ending April 20th. The annual rate of mortality in these towns, which had declined in the six preceding weeks from 35.0 to 20.5 per 1000, further fell last week to 20.3. In London the rate was 18.8 per 1000, while it averaged 21.4 in the thirty-two provincial towns. The lowest rates in these towns were 16.1 in Bradford and in Derby, 16.4 in Cardiff, 16.8 in Nottingham, and 17.0 in Oldham; the highest rates were 26.3 in Salford, 26.6 in Blackburn, 27.8 in Huddersfield, 29.7 in Manchester, and 34.5 in Bolton. The 4127 deaths included 336 which were referred to the principal zymotic diseases, against 274 and 330 in the two preceding weeks; of these, 115 resulted from whooping-cough, 89 from measles, 57 from diphtheria, 31 from diarrhoea, 24 from scarlet fever, 19 from "fever" (principally enteric), and one from small-pox. The lowest death-rates from these diseases were recorded in Bristol, Nottingham, Derby, Halifax, and Bradford; while they caused the highest rates in West Ham, Norwich, Bolton, Manchester, and Salford. The greatest mortality from measles occurred in Plymouth, Manchester, and Bolton; and from whooping-cough in Swansea, Oldham, Wolverhampton, Blackburn, Salford, and Bury. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 57 deaths from diphtheria in the thirty-three towns included 30 in London, 5 in West Ham, and 5 in Manchester. One fatal case of small-pox was registered in Liverpool, but not one in London or in any other of the thirty-three towns. There were 35 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 20th inst., against 55, 53, and 47 at the end of the three preceding weeks; 4 new cases were admitted during the week, against 11, 7, and 9 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1514, against 1555, 1519, and 1463 on the three preceding Saturdays; 162 new cases were admitted during the week, against 161, 143, and 117 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 427 and 398 in the two preceding weeks, further declined to 389 last week, but slightly exceeded the corrected average. The causes of 79, or 1.9 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns,

which had been 24.7 per 1000 in each of the two preceding weeks, declined to 21.7 during the week ending April 20th, but exceeded by 1.4 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18.2 in Dundee and 19.3 in Greenock to 21.9 in Leith and 23.0 in Aberdeen. The 623 deaths in these towns included 32 which were referred to measles, 17 to whooping-cough, 10 to diarrhoea, 8 to small-pox, 7 to diphtheria, 4 to scarlet fever, and not one to "fever." In all 78 deaths resulted from these principal zymotic diseases, against 74 and 83 in the two preceding weeks. These 78 deaths were equal to an annual rate of 2.7 per 1000, which was 1.0 per 1000 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 23 and 30 in the two preceding weeks, further rose to 32 last week, of which 10 occurred in Leith, 7 in Edinburgh, 5 in Glasgow, and 5 in Paisley. The 12 deaths referred to whooping-cough showed a decline of 13 from the number in the preceding week, and included 14 in Glasgow. Of the 8 fatal cases of small-pox 7 were recorded in Glasgow and 1 in Edinburgh. The deaths from diphtheria, which had been 2 and 3 in the two preceding weeks, further rose to 7 last week, of which 3 occurred in Glasgow and 2 in Edinburgh. The fatal cases of scarlet fever, which had been 5, 2 and 6 in the three preceding weeks, were 4 last week and included 3 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 189 and 161 in the two preceding weeks, further declined to 132 last week, but were 27 above the number in the corresponding week of last year. The causes of 27, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 43.6 to 29.2 per 1000, rose again to 29.7 during the week ending April 20th. During the past three weeks of the current quarter the death-rate in the city has averaged 34.1 per 1000, the death-rate during the same period being 19.0 in London and 20.2 in Edinburgh. The 199 deaths registered in Dublin during the week under notice showed a slight increase upon the number in the preceding week, and included 3 which were referred to the principal zymotic diseases, against numbers declining from 12 to 6 in the three preceding weeks; of these, 1 resulted from small-pox, 1 from scarlet fever, 1 from "fever," and not one either from measles, diphtheria, whooping-cough, or diarrhoea. These 3 deaths were equal to an annual rate of 0.4 per 1000, the zymotic death-rate during the same period being 1.7 in London and 2.9 in Edinburgh. The fatal cases of small-pox, which had been 3 and 2 in the two preceding weeks, further declined to 1 last week. The death referred to scarlet fever was the first recorded within the city since February last. The 199 deaths registered in Dublin last week included 39 of infants under one year of age and 65 of persons aged upwards of sixty years; the deaths of infants showed an increase, while those of elderly persons showed a further decline from those recorded in recent weeks. Two inquest cases and 3 deaths from violence were registered; and 60, or nearly a third, of the deaths occurred in public institutions. The causes of 24, or more than 12 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS AND VACCINATION IN EGYPT.

The Egyptian Sanitary Department has issued an interesting tabular statement showing the number of births, deaths, vaccinations, and revaccinations that were registered throughout the entire country during 1893 but unfortunately, owing to the non-existence of an accurate census, the compilation is shorn of well nigh half its value. The only Egyptian census of recent times was taken in 1882 the year of the Arabi disturbances, and, as might be expected, the results are now pretty generally admitted to be altogether untrustworthy. According to the 1882 estimate—for it is a misnomer to call the document a census—the population of Egypt at that time consisted of 6,817,265 souls, of whom 225,216 were said to be nomads, but the statistics now issued go far to prove that the total number of sedentary inhabitants was greatly understated. During the year 1893 314,929 births and 190,305 deaths were

registered amongst the native portion of the community. Taking the population at 7,000,000, these figures give a birth-rate of 45 and a death-rate of 27 per 1000, both far above the average; whereas if we adopt 8,000,000 as more probably representing the real number of Egyptians the ratios fall to 39.3 and 23.8 per 1000 respectively, a condition of things more in accordance with the rates obtaining elsewhere. It must also be borne in mind in this connexion that registration in Egypt is in its infancy, and that, chiefly with a view to avoid the conscription, the tendency in many districts is to avoid in every possible way the inscription of births. Returning to the document in hand, we find that 1988 foreigners died in Egypt during the year 1893; and that the births in the same category numbered 1021. As regards vaccination 300,447 primary operations were performed with success and 2391 with non-success, these totals being together equal to upwards of 95 per cent. of the births; 1686 revaccinations were carried out with satisfactory results, but in 407 instances the subjects proved refractory. At Suakin alone did the deaths (167) outnumber the births (64); and it is noteworthy that the vaccinations without success, which elsewhere were inconsiderable, should have amounted in this district to nearly one-third of the total number. The birth-rate may be said to have been exceptionally high throughout the whole country, but in Upper Egypt it was still more remarkable. In the provinces of Minieh, Assiout, Guirgneh, and Keneh there were in the aggregate 72,484 births and only 33,170 deaths, considerably less than half. At that rate the population ought to increase. From a footnote we learn that the declaration of births and deaths is obligatory among natives only. Deaths occurring amongst foreigners have, however, to be verified, and permits for burial are only issued on the certificate of a recognised medical man or sanitary agent. Natives and foreigners are alike bound by the decree which renders vaccination compulsory (Dec. 17th, 1890). To any person who was conversant with Egypt under the old régime the valuable information so unostentatiously furnished in this brief document must afford conclusive proof of the immense progress that has taken place since England entered into occupation in 1882. Ten years ago it would have been simply impossible to have rendered such a return. Ten years ago registration was practically unknown, and vaccination nearly so. The latter duty was in the hands of the village barbers, who were in the habit of keeping the vaccine—mixed with scab matter and blood—between two *plaques* of dirty glass. Immense progress has unquestionably been made, but the want of a census renders the work of the registration department trebly hard. Dr. Engel Bey has worked unceasingly and untiringly at his important task, and richly merits a reward. There is probably no country in the world where a census could be so easily taken as in Egypt, or where the cost would be less.

THE SERVICES.

ARMY MEDICAL STAFF.

BRIGADE - SURGEON - LIEUTENANT - COLONEL GEORGE ANDREW, M.B., retires on retired pay (dated April 24th, 1895). The under-mentioned Surgeon-Majors to be Surgeon-Lieutenant-Colonels:—Henry Charlesworth; John C. Dorman, M.B.; George H. Le Motte, M.D.; William L. Chester, M.B., Edward A. Mapleton, M.B.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel W. R. Hooper, Indian Medical Service, is granted the temporary rank of Surgeon-Colonel whilst President of the Medical Board, India Office. The following appointments are announced:—Surgeon-Captain J. S. S. Lumsden, to Medical Charge of the 40th Bengal Infantry; Surgeon-Captain G. H. Frost, from 22nd Bengal Infantry, to Medical Charge of the 45th Sikhs; Surgeon-Major G. S. A. Ranking, Secretary to the Board of Examiners, Calcutta, temporarily to the Charge of that portion of the office of the Home Department which is in Calcutta when the Government of India are at Simla; Surgeon-Captain C. H. James, on duty with the Sanitary Commissioner, Punjab, to officiate as Civil Surgeon of Rohtak; Surgeon-Lieutenant P. P. Kilkelly, to officiate in Medical Charge, 4th Bombay Cavalry; Surgeon-Lieutenant B. H. F. Leumann to Medical Charge, 17th Bombay Infantry; Surgeon-Captain E. G. R. Whitcombe to Medical Charge,

8th Bombay Infantry. The services of Surgeon-Captain A. W. T. Buist-Sparkes, M.B. (Bengal), are placed temporarily at the disposal of the Government of the Punjab. Surgeon-Major James Cleghorn, M.D., to be Surgeon-General and Sanitary Commissioner with the Government of India; Surgeon-Colonel D. O'C. Raye, M.D., to be Inspector-General of Civil Hospitals, Punjab; Surgeon-Colonel J. H. Newman, M.D., to be Administrative Medical Officer and Sanitary Commissioner of the Central Provinces; Surgeon-Colonel W. P. Warburton, M.D., to be Inspector-General of Civil Hospitals, North-West Provinces and Oudh. Brigade-Surgeon-Lieutenant-Colonel M. M. Galloway returns to Bombay on relief by Surgeon-Colonel Maunsell. Surgeon-Captain A. G. Moores, A.M.S., has left Lucknow for Peshawar to do duty with the General Hospital for British Troops, Chitral Relief Force. Brigade-Surgeon-Lieutenant-Colonel J. Smith, Madras, retires from the service on a pension of £500 per annum. The Queen has approved of the following promotions among the officers of the Indian Medical Service, and they are accordingly gazetted:—*Bengal Medical Establishment*: To be Brigade-Surgeon-Lieutenant-Colonel: Surgeon-Lieutenant-Colonel Frederick Augustus Smyth. To be Surgeon-Captain: Surgeon-Lieutenant Bruce Gordon Seton. *Madras Medical Establishment*: Surgeon-Lieutenants to be Surgeon-Captains: Robert Henry Elliot, Robert King Mitter, Wilfred Ernest Arbutnot Armstrong. *Bombay Medical Establishment*: To be Surgeon-Captain: Surgeon-Lieutenant William Carr Sprague, M.D. Her Majesty has also approved of the retirement from the service of the under-mentioned officer: Surgeon-Lieutenant-Colonel Thomas Robinson, Bengal Medical Establishment.

NAVAL MEDICAL SERVICE.

Fleet-Surgeon George Curtis has been placed on the Retired List at his own request, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets.

The following appointments are announced:—Fleet-Surgeon William E. Bennett to Sheerness Dockyard. Staff-Surgeons: J. L. Barrington to the *Inflexible*; C. W. Sharples to the *Unicorn*, temporary. Surgeon A. F. Harper to the *President*, additional.

MILITIA MEDICAL STAFF CORPS.

Harold Edward Mottis, Gent., to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion, the Suffolk Regiment: The under-mentioned Surgeon-Lieutenants are appointed Second Lieutenants:—Henry Cecil Harper, Charles Franklin Wright. 2nd Volunteer Battalion, the East Surrey Regiment: The under-mentioned Gentlemen to be Surgeon-Lieutenants:—Thomas Brushfield, M.B., Frederick Robert Hird. 1st Volunteer Battalion, the Royal Sussex Regiment: Surgeon-Lieutenant C. W. J. Chepmell, M.D., to be Surgeon-Captain. 1st Dumfriesshire: Surgeon-Lieutenant-Colonel J. E. Brodie, M.D., from the 3rd Volunteer Battalion, the Highland Light Infantry, to be Surgeon-Lieutenant-Colonel.

VOLUNTEER INFANTRY BRIGADES.

Clyde Brigade: Surgeon-Lieutenant-Colonel J. E. Brodie, M.D., 1st Dumfriesshire Volunteer Rifle Corps, to be Brigade-Surgeon-Lieutenant-Colonel.

THE HEMP DRUGS COMMISSION.

The Commission of Inquiry instituted by the Indian Government examined 700 witnesses. Its report, with a resolution of the Governor-General-in-Council thereon, has recently been published. As a result of the inquiry it appears that there are no such marked ill-effects, physical, mental, or moral, attendant on the use of hemp drugs as were popularly ascribed to them before the present inquiry was made. There was a complete break-down in the evidence in support of the popular impression that these drugs are a fruitful source of insanity. There has, in fact, been a great deal of popular prejudice and exaggeration as to the evil effects arising from the use of hemp drugs and ganja. Those interested in the matter may be referred to an article in the *Times* of the 22nd inst., under the head of "Indian Affairs," which deals fully with the subject. The Government of India refuses to entertain any measures for total prohibition, but is willing to put restrictions compatible with fairness on the use of hemp drugs.

FILTERS AND INFECTIOUS DISEASES.

We are glad to notice that, under the above heading, the *Pioneer Mail* of the 4th inst., calls attention to the fact that

the water filters commonly used in India are "little better than microbe traps." We have frequently adverted to this subject, and to the delusive nature of the reliance that is placed in filters in general use as a safeguard against the communication of water-borne diseases. They afford no real protection against the micro-organisms of cholera and typhoid fever. The evidence obtained in the French Army, on the other hand, on the use of the Pasteur-Chamberland filter is most favourable, and M. de Freycinet has called attention to the remarkable effect which the introduction of this filter has had in diminishing the prevalence of enteric fever in that army. We have more than once suggested that this or the Berkefeld filter, should be experimentally tried in India as a substitute for the ordinary barrack filter now used there.

LEPROSY IN INDIA.

The decision of the Government of India in regard to the leprosy question in that country, about which it will be remembered there was a Commission of Investigation some time ago, has been published in the *Gazette of India*. The Government considers that the extent to which leprosy is propagated by contagion is small, and is, therefore, unable to approve of the compulsory segregation, either absolute or partial, of lepers, except those who are vagrants. The alarm about the increase of leprosy in India is said to be groundless. The Governor-General in Council has no reason to dissent from the general conclusion of the Leprosy Commission that leprosy does not prevail in India to such an extent as to constitute a general or universal danger, and that the means by which we must look forward to secure its diminution are improved sanitation and better dietetic conditions.

DEATH IN THE SERVICES.

Deputy Surgeon-General Samuel Stacy Skipton, M.D. (retired), A.M.S., aged sixty-five, at his residence in Cheshire, on Easter Sunday. He graduated at St. Andrews University in 1852 and joined the Army in 1854. In 1866 he was appointed surgeon; was promoted to surgeon-major in 1873 and brigade-surgeon in 1884; and retired with the hon. rank of deputy surgeon-general in 1885. He was attached to the 49th Regiment in the Crimea from July 23rd, 1855, including the siege and fall of Sebastopol (medal with clasp and Turkish medal), and to the 14th Light Dragoons in the Central India campaign under Sir Hugh Rose in 1858; and was mentioned in despatches.

THE COMMANDER-IN-CHIEF.

Some of our readers will probably have noticed that Mr. Morton asked the Secretary for War whether the Commander-in-Chief was about to resign, and, if so, whether the Government intended to carry out the recommendation of the Hartington Commission. Mr. Campbell-Bannerman, in reply, said that he had no knowledge of there being any foundation for the rumour referred to. As regards the course to be followed on the occurrence of a vacancy, he repeated what he had said in September, 1893, that after the recommendation made by the Royal Commission he could not conceive of any appointment of a permanent nature being made to the post of Commander-in-Chief.

VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the under-mentioned Officers of the Volunteer Force:—*North-Eastern District: Rifle*: 2nd Volunteer Battalion, the Princess of Wales's Own (Yorkshire Regiment): Surgeon-Lieutenant-Colonel William Taylor Colby, M.D. *North-Western District: Artillery*: 5th Lancashire: Honorary Assistant Surgeon William Henry Cocker. *Eastern District: Rifle*: 3rd (Cambridgeshire) Volunteer Battalion, the Suffolk Regiment: Surgeon-Captain Francis Mears Beckett.

SALE OF POISONS IN INDIA.

Out of twenty-five cases of poisoning brought to notice last year in Burmah the chemical examiner says fifteen were cases of arsenic poisoning. This supplies, the *Pioneer Mail* remarks, additional evidence in favour of the proposals made to the Indian Medical Congress by Surgeon-Captain Evans for restricting the sale of arsenic.

The office of the Principal Medical Officer of the Madras Army is to be permanently removed from Madras to Ootacamund.

The *Malabar* sailed from Bombay on April 4th, with sixty-seven patients for Netley.

Sixteen invalids left China on April 14th for Netley.

Correspondence.

"Audi alteram partem."

"PROPHYLAXIS OF INSANITY."

To the Editors of THE LANCET.

SIRS,—Dr. Blandford, in his address on the Prophylaxis of Insanity, refers to the all-important question of marriage. In an article I wrote in the *Journal of Psychological Medicine*, vol. vii., in 1881, I gave some rules for the guidance of those who consulted me on the subject. I had previously written on the same subject in the same journal in 1875. In our present ignorance of the origin of the mysterious inheritance of disease I can only offer these rules as of approximative value. I must premise that these rules have a wide bearing, as they not only have regard to insanity, but to all hereditary diseases, for in a treatise I wrote on the Nature and Treatment of Hereditary Diseases in 1869 I contended that all hereditary diseases are interchangeable. 1. If there be a constitutional taint of any kind in either father or mother on both sides of the contracting parties, the risk is so great as almost to amount to a certainty that their offspring would inherit some form of disease belonging to the class to which these investigations refer. 2. If the constitutional disease is only on one side, either directly or collaterally through uncles or aunts, and the contracting parties are both in good bodily health, the risk is diminished one-half, and healthy offspring may be the issue of the marriage. 3. If there have been no signs of constitutional disease for a whole generation we can scarcely consider the risk materially lessened, as it so frequently reappears after being in abeyance for a whole generation. 4. If two whole generations have escaped any symptoms of hereditary disease we may fairly hope that the danger has passed and that the morbid force has expended itself.

I am, Sirs, your obedient servant,
J. M. WINN, M.D.

Goldhurst-terrace, Hampstead.

"INTERSTITIAL KERATITIS AND SYNOVITIS."

To the Editors of THE LANCET.

SIRS,—Dr. Crawford Thomson, in THE LANCET of April 6th, alluded to a paper of mine written in 1870,¹ in which I reported four cases of parenchymatous keratitis associated with acute rheumatism. Since 1870 my views on that and many other subjects have undergone important modifications. That paper was, as I now acknowledge, a somewhat crude attempt to explain what was then, and still remains, a difficult problem. The association of synovitis with interstitial keratitis was then a very unfamiliar phenomenon. Mr. Jonathan Hutchinson had indeed recorded two cases and had recognised synovitis as an occasional feature of inherited syphilis. Very few cases, however, had then been recorded, and even now their number hardly justifies the construction of a theory. I am inclined, however, to subscribe to Dr. Crawford Thomson's views as being on the whole most in harmony with the recorded facts. I would venture to put the matter in the following form. A certain cachexia, whether it be in the form of *anæmia* or *misère*, is favourable to the development of parenchymatous keratitis and to synovitis. This particular cachexia may be arrived at either by the road of inherited syphilis or by other roads, such as disordered menstruation, and a slight local exposure to irritation or injury sets up the local mischief. Still, the number of recorded cases without some indications of inherited syphilis, and even those with those indications, is so small that I do not think it is as yet safe to generalise. The proposed experiments on the joints which Dr. Crawford Thomson promises to undertake and record will be most valuable; but I cannot quite accept the conclusions drawn by Dr. Crawford Thomson from Wagenmann's experiments on the artificial production of keratitis. Dr. Crawford Thomson's paper is most suggestive, and it is hoped that his future researches may lead to some definite conclusions. There is, however, one point which should not be omitted—viz., the records of the temperature

chart. These were omitted in my four cases, as Dr. Crawford Thomson justly points out, but he falls into the same error in recording his own unique case of "unilateral keratitis with unilateral synovitis." He remarks simply that there was "no feverishness," but gives no details as to temperature, which might have afforded valuable hints, especially as to the probability of there being any rheumatic complications. In Mr. Clutton's valuable paper in THE LANCET of Feb. 27th, 1886, there is the same omission.

I am, Sirs, yours obediently,
W. SPENCER WATSON.

Henrietta-street, W., April 18th, 1895.

"THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED."

To the Editors of THE LANCET.

SIRS,—As I was a referee to the above company I have taken considerable interest in the correspondence in your columns respecting it. I think the directors must be aware, or if not this correspondence will have opened their eyes to the fact, that a class of people have gained and are gaining entrance to their medical aid society whose incomes are far from "meagre" and who are quite in a position to pay proper charges for medical attendance; and, further, that the presence of such people in a medical aid society is giving rise to a feeling in the medical profession strongly adverse to the well-being of such societies. Certain of your correspondents have pointed out instances of such abuse, and most of those who have written in defence have admitted that such abuses exist.

Now, Sirs, I have on my list many members whom I am pleased to attend for the remuneration offered by this company, but I have also on my list far too many others whose position or income is such that I would infinitely rather attend for nothing than receive the small sum paid per annum for them and consider that it discharges their obligation to myself. I quite think, Sirs, that the directors do not wish for such people, who usually enter singly; but the local agents like them—they pay regularly, do not require to be called on weekly for premiums, and insure for higher sums, paying 3d. or more weekly. In consequence of this, harm is done to the poor struggling member who has entered his wife or children, paying 1d. for each weekly as premium. The better-class or richer member entering frequently with some ailment of gravity, quite able to pay, gets and requires ten or twenty times the attendance for just the same sum as his poorer neighbour, who has entered his fairly healthy family, a uniform charge of 1½d. per week for medical aid being added to each premium, no matter what that premium may be, and so the poor man is paying for the richer, whose presence as a member is threatening the existence of a society which was established, I take it, for such people as the former. I would point out, Sirs, to the directors that a very few well-off members can do this. Say that out of a list of 100 members for whom the remuneration paid by the company at 4s. per member would come to £20 a year, there are 10 or even 5 per cent. able to pay an account of a few pounds each. This would cover, or more than cover, the yearly stipend of the whole, and a grave wrong is done to the profession. Five or ten per cent. out of the hundreds of thousands of members this company possesses would make a goodly array, and their exclusion from such societies would be a benefit alike to the really poor man and to the medical practitioner. I think, Sirs, I could show the directors a remedy to a considerable extent for this evil—namely, to make the local agents submit all proposal forms to a medical referee. I have been told that a referee, who is or was a director himself, examines everyone proposed in his district. Let the directors allow similar liberty to all referees and instruct their agents to inform all proposing to enter that the medical referee may refuse to accept or may claim the right to examine, and the well-off and the unhealthy members will disappear and the greatest grievance against this and kindred companies will be removed. I know at present the company will remove members objected to by medical officers, but in that case such members, once they are admitted, feel themselves to have a distinct grievance against the referee and company; besides, this is not going far enough: if they are to be stopped let them be stopped in the beginning before they become members, and let such companies instruct their

¹ Transactions of the Clinical Society, vol. iv., pp. 1-7.

agents that well-to-do people are not under any circumstances to be proposed for medical aid.

I am Sirs, yours faithfully,

April 22nd, 1895.

A REFUSEE.

"THE TITLE OF 'DOCTOR.'"

To the Editors of THE LANCET.

SIRS—Dr. Campbell Black in the latter portion of his letter in THE LANCET of March 16th has exposed an old sore without suggesting a likely remedy. Practice for gain in any department of medicine or surgery is not forbidden by law to persons who do not possess a valid qualification; and so long as he does not pretend to be legally qualified by adoption of titles specifically designated in the Medical Act there is nothing to prevent any individual, educated or not educated, from practising. The law is also very largely violated with impunity because there exists no public body or functionary charged with its enforcement; but the fact that the Dental Association, which has taken up the duty of public prosecutor on behalf of the speciality, has never ventured to attack one of the numerous unqualified quack dentists who adopt the title of Doctor is enough to suggest the difficulties which lie in the way of vindication of the law. That construction of laws for protection of the public and professions is not beyond the power of statesmen is sufficiently evident. An attempt by an unqualified man to practise as a solicitor meets with speedy punishment, and such an abuse as assumption of titles and practice by unqualified adventurers in the legal profession is virtually impossible. By the Veterinary Surgeons Act, 1831 similar protection is afforded the veterinary profession, and under it unqualified farriers have been punished merely for displaying a sign inscribed "Veterinary forge." The public are thus prevented so far as possible from mistaking unqualified pretenders for educated practitioners; and dumb brutes are also thus far safeguarded against the torments which unscientific "veterinary surgery" so often inflicts upon its victims. The Medical Act devised to provide for men protection the same as the Veterinary Act affords to brutes dates from 1858; the Dentists Act from 1878. Under neither of these Acts has any serious attempt been made to check the evils they were intended to prevent; and in no instance have proceedings under these Acts been taken against infamous quacks known to professional authorities, and often to the police, as men openly pursuing a career of crime. It can, I believe, be proved that quackery forming a potent factor in deterioration of the public health puts money ultimately into the pockets of legitimate practitioners; but if the unselfishness of the profession in seeking to put a stop to glaring abuses cannot be proved it can at any rate be demonstrated that enforcement of stringent laws would operate in the main for the benefit of the classes whose claim upon the guardianship of the State is surely paramount. It can hardly be believed that amendment of the law would be long delayed if once the case, supported by the voice of the profession, were fully and fairly laid before the Legislature.

I am, Sirs, yours faithfully,

Cavendish-square, March 16th, 1895.

HENRY SEWILL.

To the Editors of THE LANCET.

SIRS.—Mr. J. B. Pike deserves the thanks of all lovers of justice for his able and spirited defence of the rights and privileges of physicians. It is a fact well known to the public and the profession that a physician is a doctor, though it is not every doctor who is a physician. Let me recommend all carping critics to look out the word doctor in any good English dictionary, and then reflect upon their own small-mindedness. Until the year 1859 it was a *sine qua non* that a candidate for the L.R.C.P. Edin. should be an M.D.; and no M.D., no matter how eminent a university, could practise as a physician within the jurisdiction of the Edinburgh College without its licence. Until the last score of years or so the Dublin College of Physicians actually granted by its Charter to its licentiates the title of "Doctor of Medicine." At the passing of the Medical Act of 1858 it was the custom of the London College of Physicians to address all licentiates as Doctor, and in many old medical works by the most eminent of the profession in London may be seen upon the title-page, after the author's name, "M.D. of the College of Physicians of London." Now it may be readily seen that all this is so merely because it has been for generations the polite custom to style a

physician by the courteous title of Doctor, and this title has become a part of the rights and privileges of physicians from ancient usage. It is still more important in these days that all duly qualified physicians should do their utmost to uphold the dignity and status of their several Colleges, when so much of their powers was allowed to lapse by the passing of the Medical Act in 1858, and thereby M.B.'s and M.D.'s were permitted to practise medicine in all parts of Her Majesty's dominions without being first licensed by one of the Colleges of Physicians; and it should be borne in mind that an M.B. or an M.D. in virtue of such degree alone is not legally entitled to call himself a physician any more than an LL.B. or an LL.D. is entitled to call himself a barrister. It is not every barrister who is an LL.D., nor is it every physician who is an M.D. From time immemorial barristers have been called counsel, and from time immemorial physicians have been called doctors; and as it is the custom of Bachelors of Medicine to assume the title and prefix of Doctor (even in the face of by-laws of the Universities specially directed against such a practice), it cannot in common fairness be objected that Licentiates in Medicine should use the same title upon the strength of their being physicians. For the information of Dr. D. C. Black, M.D., whose letter of March 16th I have only just read, I should like to state, as an outsider, that I am not surprised at his two motions submitted to the Faculty of Physicians and Surgeons of Glasgow being rejected by a majority, because, with regard to the first, it was a self-evident fact that Licentiates of the Faculties, being surgeons, are not as such entitled to be styled Doctor; and, with regard to the second, that, two other independent Colleges being concerned, such a motion could not be regarded otherwise than as a gratuitous insult to those two Colleges, whose licentiates would probably deem it a piece of unwarrantable interference upon the part of the Faculty had such a motion been carried. I quite agree with Dr. Black that "if the mere Licentiate of the Faculty is to be permitted to assume the title of 'Doctor' on the strength of a single surgical qualification, what is to prevent the L.R.C.S. Edin., the M.R.C.S. Eng., the L.S.A., and the L.A.H. Dub. from doing the same thing?" But, Sirs, I take it that this is not the real point at issue, and I am humbly of opinion that if the governing body of the Faculty at Glasgow, together with the other medical corporations and medical faculties in the universities, would direct their attention to the putting down of quackery, the detection of bogus M.D.'s and of unqualified and illegal practice of all kinds, so rampant in advertisements particularly, they would earn the admiration of the profession generally, including that numerous body, the physicians, who are doctors but not M.D.'s.

I am, Sirs, yours faithfully,

Ramsgate, April 22nd, 1895.

CHARLES COTTON.

P.S.—As a remedy for this complaint, which is extremely chronic, I would like to suggest to all those of the profession who are interested in this matter that they should loyally place as affix to their names the source from which they derive their prefix, as, for example, the M.D. Lond. would appear as Dr. Blank, M.D. Lond.; the M.B. Oxon. as Dr. Blank M.B. Oxon.; the F.R.C.P. Lond. as Dr. Blank, F.R.C.P. Lond.; the L.R.C.P. Edin. as Dr. Blank, L.R.C.P. Edin., and so on. If this were universal, I feel sure that the petty jealousies of angry and disappointed men would no longer be periodically aired in the medical press; that the public would then be able to understand what their medical adviser really was; and that medical titles would become really titles of honour and like the various titles of knighthood, all of which have a common prefix but are vastly different in their sources, as, for example, the ordinary knight bachelors, bannerets, baronets, and those of the well-known orders.

"PROVISION FOR YOUNG IMBECILES."

To the Editors of THE LANCET.

SIRS.—I was very glad to see in your issue of the 30th ult. that Dr. Shuttleworth had drawn attention to the want of proper provision for young imbeciles. The question has been too long neglected. Four years ago, speaking at the North-Western Poor-law Conference, I drew attention to the fact that England will very soon have to take, not a second, but a fifth or sixth place as regards provision for the feeble-minded and epileptic. Four years ago a Bill was brought before the French Parliament, the first clause of

which reads as follows: "Chaque département est tenu d'avoir un établissement médical, destiné à recueillir les idiots et arrétés, à les éduquer et à les doter d'un métier manuel. Plusieurs départements pourront se grouper pour ouvrir cet établissement à frais communs." The Bill has since been amended so as to compel each department to provide two buildings, one for ordinary idiots and the other for epileptic idiots, and with this amendment I thoroughly agree on account of the pernicious effect that the association of epileptic and non-epileptic idiots has upon such cases. The cry has been raised against county councillors who, like myself, advocate proper provision that we are proposing to spend an enormous sum of money for which there would be no return. I believe that those who raise that cry are utterly ignorant of what they are talking about or they would know that the want of proper provision for these cases throws a very heavy burden upon the poor-rate. Returns obtained from the various boards of guardians show that in one year 715 weak-minded women passed through 105 workhouses, and at 56 workhouses it was stated that 366 of these women were leading immoral lives. Anyone who will take the trouble to go through the cases of weak intellect that were noted by the Metropolitan Association for Befriending Young Servants will find case after case where the mothers of illegitimate feeble-minded children are in the asylum or the imbecile wards of the various workhouses—a life-long burden on the ratepayers. It is not only the numbers in the workhouses we have to think about; there are large numbers of these cases at home where it is utterly out of the power of the parents to give them that amount of education which they are capable of receiving. The result is that as years roll on and the parents die these cases come on our asylum books. I am very glad to think that a very large number of the Lancashire boards are in favour of proper provision, and the matter is now under the consideration of the Plans Committee of the Lancashire Asylums Board, and I have little doubt but that practical results will follow.

I am, Sirs, yours truly,

JNO. MILSON RHODES, M.D. BRUX.,

Chairman of the Chorlton Board of Guardians.
Didsbury, Manchester, April 20th, 1895.

"DISLOCATION OF THE LOWER JAW DURING AN EPILEPTIC FIT."

To the Editors of THE LANCET.

SIRS.—Mr. C. F. Beadles mentions a case of this kind in THE LANCET of April 20th. Allow me to name another. A woman aged thirty-two, weak-minded, an epileptic since ten, dislocated her jaw in a fit four years ago; it was replaced with some little difficulty. Since then the same accident has occurred frequently, and now it does so once or twice a week. And the patient can and does produce it at will; if she is put out she will put her jaw out, and thus signify her displeasure. She is also able to reduce it herself.

I am, Sirs, yours faithfully,

Hornsey-lane, N., April 22nd, 1895.

EDWARD CALTHROP.

"THE WOMEN'S FREE HOSPITAL, SOUTHAMPTON."

To the Editors of THE LANCET.

SIRS.—Our society have no intention of carrying on a newspaper correspondence with the committee of the Women's Hospital, for the truth cannot be elicited in that way. We must, however, mention that the resignations from our society, of which the hospital committee endeavour to make a strong point, were not of "senior members of the society" but simply of four non-resident members. Our society have acted in what they consider to be the public interest in demanding an inquiry. They have brought grave charges against the hospital—namely: (1) That the unusual frequency of operations performed and the number of instances in which operations have been advised though not performed, and now proved to have been unnecessary, taken in conjunction with the admission of the hospital committee that proper consultation has frequently been omitted, give rise to a grave suspicion that some of the operations have been unjustifiable; (2) that the management of the hospital is unsatisfactory; and (3) that the financial arrangements are incompatible with the term "free." And this society would add

that the omission of all mention of operation in the death certificates of certain patients who have died after operation is irregular and much to be deprecated.

If the committee of the Women's Hospital believe, as they say, that the action of the Medical Society is the result merely of a mean and despicable professional jealousy, and if, as they further say, the committee of the hospital have nothing to conceal, let them show the courage of their opinions and agree to an inquiry being held by impartial and competent persons. The Medical Society is prepared to justify its position before any such tribunal; but the suggestion that the hospital committee, who are accused of mismanagement, should sit in judgment on themselves is obviously absurd. If the committee of the hospital prefer that the matter should be thrashed out in a court of law, let an action for libel be brought. Our society will defend such an action and plead that the statements they have made are true in substance and in fact. Unfortunately, our society has no power to force an inquiry, but if after this the hospital committee decline it, the medical society and the thinking portion of the public will need no stronger evidence to convince them that there is something to conceal, notwithstanding the statement of the hospital committee to the contrary. The medical society has now discharged its duty to the public and to itself, and declines to have any further correspondence with the hospital authorities, except for the purpose of an inquiry.

We are, Sirs, yours faithfully,

R. D. H. GWILLIM.

NORMAN ALDRIDGE.

April 24th, 1895.

Hon. Secs., Southampton Medical Society.

To the Editors of THE LANCET.

SIRS.—With reference to a letter from Dr. Playfair in your issue of April 20th, I beg to say that a reply will be sent at as early a date as possible.

I am, Sirs, yours faithfully,

H. C. PHILLIPS, Hon. Sec.

Clifton-villas, Hill-lane, Southampton, April 24th, 1895.

PUBLIC AND PRIVATE VACCINATION.

To the Editors of THE LANCET.

SIRS.—As a public vaccinator I must protest against the doctrine of voluntary vaccination as put forward by a correspondent in your last issue. The fault lies in the law and not in the operation or operator—i.e., while it is compulsory on the part of public vaccinators to put from three to four or more vesicles on the arm the private practitioner revels in uncontrolled liberty, and virtually does as his patient bids him. I know a public vaccinator who puts on the regulation quartette in his official capacity, and actually stops at two where the mother backs her request or command with half-a-crown. Surely the law is faulty here, and the less said about the operator the better. The medical conscience is as elastic as the general conscience, and it never more required a tonic of the moral kind than in the present day.

I am, Sirs, yours faithfully,

April 23rd, 1895.

PUBLIC VACCINATOR.

LIFE ASSURANCE SOCIETIES.

To the Editors of THE LANCET.

SIRS.—I enclose copy of a letter received by me from an insurance agent in the neighbourhood. If his statement as to other medical men is true, which I doubt, it is evident that the medical profession has only itself to blame for its diminishing income. The only reason for thus sharing the fee is the hope of taking these cases from a brother practitioner; and this almost dishonest sharing is therefore a dead loss to the profession at large. I sent the letter to the head office, and received an answer expressing astonishment and repudiating and condemning any such arrangement.

I am, Sirs, your obedient servant,

DEVONIAN.

April 5th, 1895.

DEAR SIR.—In the event of my getting any life assurance proposals in your district, would you be willing to do as other medical men—allow me half your fee for examination? The fees are, as you know, 10s. 6d. for £100. Hence, if any one insured for £100 the fee would be 10s. 6d. Would you take 5s. 3d. and allow me the other 5s. 3d.? I enclose stamped and addressed envelope for your reply.—I remain,

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Effect of a Dream.

LOVERS of the marvellous have the opportunity of finding a strange coincidence in a story recently told at the coroner's court here. A girl aged thirteen disappeared from her home; her disposition was taciturn and sulky, which, coupled with her expressed apprehension of water, led to the worst fears being entertained by her parents. Her body was subsequently found in the canal. The aunt of the deceased, hearing that the girl was missing, dreamt that she was walking along the bank of the canal, and while looking into the water saw the face of her niece. The police were asked to drag the canal at the spot indicated in the dream; they did so, and at once found the body. Such was the simple story told at the inquest, a statement which if made in a novel would be ascribed to the powers of the writer's imagination.

Death of Mr. John Baines.

At the age of seventy-six this well-known figure in the local medical profession passed away on the 20th inst. Mr. Baines was essentially a type of the old school. Disdaining the aid of horses he daily walked his round for many years. His advice was held in high esteem by a large number of the poor, by whom he was considered a high authority, particularly in cases of midwifery. His habit was to wear a full coat with pockets arranged all round, containing midwifery forceps, bottles, and a number of useful things, not the least important of which was a gimlet which he was wont to stick into a convenient place to hang up his coat. In some of the poorer tenements he visited this precaution was one which commended itself, and in many ways proved of value. His genial form and kindly manner will be missed among a considerable number of the working class in the town.

Female Slavery.

The periodical discussion about the long hours of shop assistants has lately been revived. The tendency of things to find their level by the ordinary action of supply and demand appears to be unequal to the solution in this instance. Too many female shop assistants and not enough servant girls—this is the main cry. Some are disposed to add to the category of ills of these two classes the grievances of nurses and teachers. With some show of reason it is argued that nurses who have to walk long distances to attend to their patients necessarily arrive in a tired and often jaded condition, in which their services cannot be adequately rendered. No doubt under these circumstances the patients suffer. The remedy could well be applied by limiting the area of their duties, which would mean an increase in the number of nurses in any given district. Occupation, and efficiency in the work done would be the outcome of a laudable policy, which would result in a greater good to a greater number.

Saltley Sewage Farm.

The work of the Tame and Rea District Drainage Board, which comprises in its area the disposal of the sewage of Birmingham and adjacent districts, is of an extensive and interesting nature. The board carries on an extensive market gardening business, as well as that of stock-breeding and feeding, milk selling, and fruit growing. The farm consists of 1300 acres, of which 800 are irrigated by gravitation, 247 are occupied by roads, buildings, works, &c., and fifty-three are of turf for grazing &c. The labour on the sewage farm costs about £6 per acre. Various details connected with the produce and its value have been set forth in an interesting manner, which affords matter for comparison of agricultural items, and will repay perusal. The total amount of loans negotiated on account of the farm is £426,115 and the whole of that amount has been expended. The sum contributed by the rates is about £34,000 per annum. The average loss on the farm accounts for the last seven years has been £2688 per annum, many reasons of a satisfactory kind being adduced to account for this deficit. It is stated that the area of the farm is to be increased soon by 180 acres, arrangements for the purchase being already made. An undertaking of such magnitude possesses an interest for the ratepayers, and affords ground for reflection in times of depression in trade and agricultural competition.

April 23rd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Death of the Rev. Canon Whitley, D.D.

ON Monday last, at the vicarage of Bedlington in Northumberland, died the Rev. Canon Whitley at the ripe age of eighty-seven years. There was no better known or more universally beloved clergyman in the north of England than the deceased canon. Senior wrangler in 1830, he came to Durham in the year 1833 and was intimately connected with the University from that time till 1855. In 1854 he became vicar of Bedlington. At the death of Dr. Headlam, the first President of the College of Medicine at Newcastle-upon-Tyne, Dr. Whitley, then an honorary canon of Durham, was unanimously elected President, and continued in office from 1864 till the year 1872, when he was succeeded by the late Dr. E. Charlton. At Bedlington Dr. Whitley was identified with every public movement. For many years he presided at the Bedlington Petty Sessional Court and at the local board. Last year he laid the foundation stone of the local waterworks, when he was presented with a silver trowel by Mr. J. Trotter, who finished his remarks with the following words: "In short, the name of Canon Whitley was a household word in every house in the district, and was synonymous with all that was good, just, and benevolent." Few of the men with whom the Canon was intimate remain, but his old friend and colleague, Dr. Dennis Embleton, is still in Newcastle, the Nestor of his profession. Canon Whitley might have been with us yet but for an unfortunate accident. A few weeks ago he fell whilst alighting from his carriage, and the shock so upset him that he died.

Dental Hospital for Newcastle-upon-Tyne.

In these days of special hospitals it is strange that a city of the size of Newcastle should be without a dental hospital. It is mainly due to the energy of Mr. Markham, a leading dentist in Newcastle, that yesterday the Right Worshipful the Mayor opened, in a prominent thoroughfare, a dental hospital for the town and district. The movement has been well supported by the dentists, and there can be no doubt that the hospital will be a great success and a boon to the poor of the neighbourhood.

Illegal Sale of Chlorodyne.

At the Newcastle-upon-Tyne county court a few days ago a druggist's assistant was prosecuted by the Pharmaceutical Society for selling chlorodyne. The defence was that the assistant thought the drug was a patent medicine. A fine of £5 was inflicted by Judge Greenwell, and his honour remarked, "An apprentice is absolutely prohibited from selling poisons." Considerable importance must be attached to this action of an apprentice by the Pharmaceutical Society, as a barrister was sent from London to conduct the case.

Newcastle-upon-Tyne, April 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University General Council.

THE statutory half-yearly meeting of this body was held last week, and as there was no business of outstanding importance there was a small attendance. Sir William Muir presided. The report by the committee on ordinances was submitted, and dealt with the ordinances issued since last meeting of the council. The ordinance dealing with the powers of the chairman of the general council had been modified in the direction recommended by the council. Approval was expressed of a new ordinance repealing a section of a previous one in which it was provided that "no person shall be appointed an examiner who is not a member of the general council of one or other of the Scottish Universities." The report of the finance committee was then submitted, which shows that last year there was a surplus of £4500. It states that "the expenditure continues to show a tendency to increase, as is obviously necessary if the University is to maintain its high standard of efficiency in competition with other academic institutions. In particular the staff of lecturers has been and is being considerably increased. It is perhaps not strictly within the province of the committee to

criticise the *personnel* of the appointments which have in some cases been made to lectureships, but they desire to say that the method frequently adopted of appointing a professor's assistant to lecture upon a subject cognate to the chair is not calculated to achieve that independence of thought and action which is needed for the higher and specialised branches of knowledge." The total number of students in medicine was last year 1560 against 1951 in 1891-2 and 1736 in 1892-3.

Unusually High Death-rate in Edinburgh.

During the month of March the total number of deaths was 820, making a death-rate of 35.97 per 1000. From 1890 to 1894 the death-rate varied from 15 or 16 to over 20 per 1000 during the corresponding month. The deaths from diseases of the chest were 438 and from zymotic diseases 111. The zymotic cases included 85 from measles, 6 from scarlet-fever, and 4 from small-pox.

Graduation Ceremony at Edinburgh University.

The spring graduation ceremony took place last week, the ceremony at this time being mainly for the conferring of honorary degrees and degrees in arts. Professor Seth delivered the address and dwelt upon the changes in the arts curriculum brought about by the Universities Commission.

Memorial to Dr. Peter Lowe.

A tablet to the memory of Dr. Peter Lowe, the founder of the Faculty of Physicians and Surgeons of Glasgow, has recently been erected in the nave of the Cathedral as the result of a movement on the part of the council of the Faculty. Dr. Lowe was buried in the Cathedral churchyard, one of the prominent features in which is a quaint and curiously carved monument erected over his grave. This monument bears the date 1612, and it is its somewhat time-worn condition that has suggested the necessity for another memorial. This has taken the form of a magnificent bronze tablet set in a marble slab; it bears in relief a number of figures, the principal one symbolising the spirit of healing. Underneath is the inscription copied from the old tomb. The ceremony of unveiling was performed by Dr. Bruce Goff, the President of the Faculty, in the presence of a number of the leading practitioners from Glasgow and the neighbourhood.

Graduation Ceremony at the Glasgow University.

The spring graduation ceremony took place on the 17th inst. As is usual at this time of the year the great majority of the graduates came from the Arts and Divinity Faculties. Six gentlemen, however, received the degree of M.D., one of these, Dr. P. H. Abercrombie of London, being awarded commendation for his thesis on Turbinotomy in Nasal Stenosis: analysis and notes of sixty-six cases. Amongst those who received the honorary degree of LL.D. were Professor Thorpe, F.R.S., chemist to the Inland Revenue Department, Somerset House, and Dr. Laurence Waddell, I.M.S. The last mentioned is a graduate in medicine of the University, and during his residence in India has distinguished himself by his studies of natural history and of the native religions. One specially interesting feature of the ceremony was the "capping" of two ladies, each of whom received the M.A. degree. These are the first ladies who have taken the arts degree in the University of Glasgow. Medicine has here been beforehand, the Queen Margaret College of the University having provided four medical graduates in 1894.

The Medical Schools, Glasgow.

The summer session at the University and the extra-mural schools commenced on the 22nd inst. At Anderson's College several changes in the teaching staff have taken place. Dr. T. K. Dalziel (who has previously lectured on forensic medicine) has been appointed lecturer on Surgery in the place of Dr. James Dunlop, resigned. The vacancy thus created in Forensic Medicine has been filled by the appointment of Dr. R. M. Buchanan. Dr. Erskine takes the place of Dr. Barr (transferred to the University) as lecturer on Diseases of the Ear; and Dr. Pearson Munro becomes lecturer on Public Health.

Presentation to Dr. T. K. Dalziel.

The members of the Glasgow Police Force have presented Dr. T. K. Dalziel with a handsome hall clock bearing a suitable inscription on the occasion of his retirement from the post of casualty surgeon to the central police division. Dr. Dalziel has held this position for ten years, and one of his duties has been the instruction of the police in ambu-

lance work. The presentation was made by Superintendent Orr.

Clinical Demonstrations for Practitioners.

The members of the Glasgow Southern Medical Society, on the invitation of Dr. Middleton, substituted for their usual evening meeting on the 11th inst. a clinical demonstration in the Royal Infirmary. Dr. Middleton showed a number of patients, charts, microscopic specimens, &c., and in the course of his remarks expressed the opinion that it would be a great advantage to many members of the profession and would considerably extend the usefulness of the hospitals if some arrangement were made by which the practitioners of the city could have an opportunity of systematic attendance on clinical work in the infirmaries. He thought this could only be done satisfactorily by appointing a certain hour, say one day a week, when the physician in charge of the wards would attend and give demonstrations specially for practitioners; qualified medical men could not be expected to attend at the ordinary clinical instruction of medical students, and moreover, elementary teaching was not what was required. If his suggestion was adopted they would have something in the shape of a permanent post-graduate clinical course. On the motion of Dr. John Brown, the President of the society, a cordial vote of thanks was passed to Dr. Middleton for his instructive and interesting demonstration, and the members generally expressed warm approval of his proposal to increase the facilities for post-graduate clinical work.

Glasgow: Women Candidates for the Triple Qualification.

As showing the increasing popularity of medicine as a career for women, the number of women amongst the successful candidates at the April examinations for the Triple Qualification is somewhat striking. In the Final Examination of 44 successful candidates 6 were women; in the Third Examination the women numbered 6 out of 11 successes; in the Second 6 women passed and 22 men; and in the First the numbers were 5 women and 7 men.

The Royal Infirmary, Dundee.

About the end of the present year the Dundee Royal Infirmary will be in possession of a new operating theatre, designed according to modern requirements and embodying all the most recent suggestions and improvements. It will be a spacious, well-lighted room, provided with seats for forty students; the floor will be made of Taratza and will measure thirty feet by twenty-five; the walls will be covered with smooth tiles. Ample provision has been made for the admission of light; there will be a large circular skylight in the roof, a very wide bow-window on the north side, and a smaller window on the west side. Between the wards and the theatre is the anæsthetic room, the communication of which with the theatre is closed by an iron folding door. The washing basins are of glass and their waste-pipes discharge outside into the open air. Arrangements will be made for promptly washing every part of the interior of the theatre with a hose-pipe. There is a special room for the sterilising of instruments and dressings. Both gas and electric light are provided, and warmth is supplied by steam pipes and radiators. The estimated cost of the new structure is £1500.

April 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Treatment of Hydrophobia.

At a meeting of the Armagh board of guardians, held on April 16th, a resolution was carried unanimously that as, owing to the absence in Ireland of any Pasteur institution for the treatment of hydrophobia, patients have now to be sent to Paris at large expense and often at great personal inconvenience, the time has come when a Pasteur Institute should be established in Dublin, and that the Local Government Board be requested to take such steps as may be necessary to meet so grave a public requirement.

Omagh District Lunatic Asylum.

At the last monthly meeting of the governors of this asylum it was decided to increase the salary of the assistant resident medical superintendent, Mr. West, to £215 per annum.

North of Ireland Branch of the British Medical Association.

The spring meeting of the above society was held in

Belfast on April 18th and was largely attended. Dr. Lindsay introduced a discussion on Pneumonia, dealing with a variety of its features, as bacteriology, etiology, temperature, diagnosis, treatment, &c.; and Professor Whitley, Dr. Thompson (Omagh), Dr. Calwell, Dr. Bingham, Dr. Boyd, and Dr. Dempsey also spoke. Professor Byers then read a paper on Recent Views as to the Management of Labour, in which, amongst other matters, he dwelt fully on the great importance of abdominal palpation in the conduct of labour, a method which gave more information than vaginal examination to the medical attendant, and was safer for, and less objectionable to, the patient herself. In the discussion which followed Dr. Fraser, Dr. Kevin, Dr. Darling (Lurgan), and Dr. Dempsey took part. Dr. Howard Sinclair showed a case of Spastic Paralysis in a child; Dr. Darling, a huge Fibroma of the Ovary; and Professor Byers, the specimens (Cystic Ovaries, Papilloma of Fallopian Tube and Broad Ligament, and portion of Enlarged Uterus) removed in a case of double ovariectomy and hysterectomy. It was decided that in future the meetings of the North of Ireland Branch shall be held at twelve o'clock, as at this time country members will be better able to attend.

Downpatrick Water-supply.

At the meeting of the Downpatrick board of guardians held on April 20th a declaration in reference to the present state of the storage reservoir at Tanaghmore was received from Dr. Heron and Mr. Maguire, two of the members of the Ratepayers' Protection Committee, and was ordered to be inserted on the minutes. Among other matters they say the greater part of the reservoir bottom consists of soft peat bog without any firm skin or upper layer on it; and that portions of the surface appear to have been loosely sprinkled with stones forming a single thin layer wholly insufficient as a covering for the bog to keep the water from contact with it and consequent pollution. The water that remained in the reservoir they found exceedingly foul and exhibiting a scum on the surface, and showing evidence of contact with boggy material.

The Ambulance Waggon.

In 1892 one of the Belfast merchant princes, Mr. Allen, of Stormount Castle, presented a fully-equipped ambulance to the city. This was on Aug. 2nd, 1892 and during the remainder of that year it was called upon 16 times. In 1893 there were 45 calls; in 1894, 392 calls; and up to the present date of the current year, 191 calls; in all, 644 sufferers have been relieved since Mr. Allen's gift. The expense of the horsing and the working of the waggon has been met by the Police Committee of the City Corporation, who gave it in charge to the Fire Brigade. Mr. Parker (the superintendent of the Fire Brigade), himself an enthusiast in ambulance work, and his men, who have been trained in ambulance work by Dr. H. L. McKisack, have undertaken this duty, and are doing it most admirably. It became evident to the city coroner, Mr. Finnegan, that a second ambulance would be needed, and he brought the matter before the local committee of the St. John Ambulance Association, who cordially approved of the scheme, and appointed a subcommittee to carry out the project. The coroner raised the necessary funds for the purchase of the new waggon, which on April 20th was named "Londonderry" by the Marchioness of Londonderry. In doing so she said she was herself the proud possessor of the certificate of the St. John Ambulance Association. She trusted the waggon would be the means of relieving a great deal of suffering in the future. The ambulance vehicle is the largest pneumatic-tyred in the world. The body of the carriage has been made lofty to obtain the very best ventilation. It will carry two patients, with one, two, or three attendants. The springs are specially made to prevent vibration, and the wheels are rubber-tyred so as to minimise noise. The wood work is of ash panelled with walnut and highly varnished, so that it can be washed and disinfected if necessary. There is a folding step to work with the doors as they open or shut. Altogether, it is a most perfect machine of its kind.

The Mountstewart Boating Accident.

Nothing further has transpired in reference to the sad boating accident to Lord Londonderry's servants at Strangford Lough, County Down. It is said that an oar and a luncheon basket have been found, but no clue whatever has been discovered as to the bodies, and the report that the boat has been found is not correct. There is an extremely strong current at the mouth of the Lough, running at the rate of ten miles an hour between Portaferry and Strangford, and it

is feared that the bodies may have been carried out to sea by the tide.

The Cork Mercy Hospital.

The annual report of the Mercy Hospital has been issued by the board of governors. It points out that the hospital has been enlarged by the addition of two private houses adjoining it. The number of surgical and medical extern patients has diminished somewhat owing, it is suggested, to a change in the hours of attendance; but a large increase has taken place in the department for diseases of the eye, ear, and throat, the numbers recorded for that special branch being 14,453 externs last year and 11,432 the previous year, and 134 operations this year and 22 the previous year. The balance-sheet showed that the hospital is in a healthier condition financially than it had been some previous years. An anonymous correspondent writing to one of the daily papers directs attention to the above figures, and makes the modest proposition that part of the funds specially collected for the Ophthalmic Hospital should be handed over for the benefit of the Mercy Hospital.

A Strange Case of Attempted Suicide.

A gentleman holding a very important Government appointment endeavoured to commit suicide in a wood near Crosshaven under very sad circumstances. Owing to his mental condition having caused grave anxiety to his relatives special precautions were taken for his protection; but he managed to elude the vigilance of his attendant, and when discovered it was found that he had cut his throat with a razor and inflicted frightful wounds on his face and left forearm. It was afterwards ascertained that prior to leaving his residence he had tied his hands together, and the wound on his left forearm was probably inflicted in the endeavour to set himself free. From a psychological point of view it would be interesting to analyse the train of thought that passed through the unfortunate patient's brain prior to his having tied his hands. Did he feel that he was being goaded on to suicide by an irresistible impulse, and whilst reason was still comparatively dominant did he take such precautions as he could devise for his safety; or, on the other hand, which is perhaps less likely, was he anxious to save his relatives from the stigma attaching to suicide, and did he endeavour to make the case appear to be one, not of self-destruction, but of murder? The desire to save the feelings of relatives was singularly exemplified some years ago by the action of a distinguished gentleman who committed suicide and had left beside him a slip of paper on which was inscribed the one word "Mad."

Rabies in Cork.

Rabies is causing a good deal of concern to some of the boards of guardians in the county of Cork, as, apart from any other consideration, the amount of expenditure involved is becoming considerable. If the guardians order the destruction of animals bitten by a rabid dog they are obliged to recompense the owners; but the principal expense is incurred in sending to Paris any of the poorer classes who may have been bitten by rabid dogs. The usual custom is to have the patient accompanied by a relieving officer, and travelling expenses, together with the cost of maintenance, come to a considerable sum.

The Local Government Board sent a communication to the Bansha Dispensary Committee informing them that Dr. Browne, medical inspector, had reported that on visiting Bansha Dispensary he found the medical officer in a most excited state and evidently suffering from mental aberration. The inspector recommended that the medical officer be relieved from duty, and the committee at once acted on the suggestion.

April 23rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Influenza followed by Infection with Bacillus Coli.

DR. SIREDEY¹ had recently under his care a man aged twenty-nine who, admitted into hospital on the fifteenth day of a well-marked attack of influenza, with slight congestion of the lungs and very limited effusion into the left pleural cavity, had besides a temperature oscillating around 40° C. (104° F.), and also intense albuminuria and symptoms of

¹ Société Médicale des Hôpitaux, April 19th, 1895.

serious general infection of the system. Despite the absence of typhoid stools, the onset of coma on the third day after admission led to puncture of the spleen for diagnostic purposes. The product of the puncture yielded no trace of Eberth's bacillus, but there was discovered the bacillus coli, which was also found in the urine and in the blood of the lungs. The man died with uræmic symptoms. The necropsy failed to bring to light any typhoid lesions. The left kidney was the seat of intense inflammation, there being present also a voluminous white infarct. This case reminds one of the forms of infective nephritis studied by Vidal, and which were characterised by typhoid symptoms. It is probable that many infective diseases besides influenza end fatally on account of the onslaughts of this mischievous germ on enfeebled tissues.

Microbes and Wood Pavement.

The grave charge has been formulated against wood pavement of constituting a favourable nidus for the cultivation of germs; indeed, the theory has been advanced that the serious epidemic of influenza that visited this capital in 1889-90 owed its inception to this cause. M. Miquel now comes forward to reassure us on this head by proving experimentally that wood paving is not so deleterious to public health as has been represented. A décigramme of sawdust is collected from the bottom of a hole bored into the wood pavement by means of a drill sterilised in a flame and then allowed to cool, the sawdust is diluted with 100 c.c. of sterilised water, and the mixture is sown on nutritive gelatine. The number of colonies is counted at the end of thirty days of culture at a temperature of 20° to 22° C. Newly laid pavement composed of pine blocks yields a dust at a depth of 3 centimetres which gives 650 germs per gramme of dust, or rather less than one per milligramme. Pavement laid six, eight, or nine years ago was likewise examined, care being in this case taken to remove by previous scraping to a depth of 1 or 2 millimetres the superficial crust developed by the traffic. In the pavement of the Faubourg St. Honoré, composed of Landes pine and laid in 1887, 1 gramme of sawdust at the surface produced 1,400,000 bacteria. At a depth of 5 centimetres this number had diminished to 4200. In pitch-pine pavement laid in 1889 in the Rue St. Lazare and the Rue de Rome the superficial sawdust yielded per gramme 1,004,000 bacteria, whereas at a depth of 2 centimetres only 500 were found. In the same way the Rue Marbeuf pavement, laid in 1886, gave at the surface 1,365,000 germs per gramme, and 4200 and 3100 at depths of 2 and 5 centimetres respectively. This goes to prove that wood pavement does not allow any penetration of germs, which remain adherent to the superficial layers. Paris mud, dried at a temperature of 30° to 35° C. yields an average per gramme of pulverised mud of from 40 to 50 million bacteria.

Antistreptococcic Serum.

Inquiries having been addressed from England to Messrs. Roberts and Co., the well-known chemists of the Rue de la Paix, regarding the possibility of procuring a supply of this product, the matter was referred to me. I at once wrote to Dr. Roger, a translation of whose courteous reply I append for the information of your readers:—

"4, rue Perrault.
"DEAR FRIEND,—Heartily thanks for the note which you addressed to THE LANCET, and I am very glad to learn that English medical men have taken an interest in my modest researches. Until now I have vaccinated only two horses, these providing me with quite an insufficient amount of serum; the animals are bled every fortnight or twenty days, and at present I furnish those medical men with serum who require it. But, as you see, no practical solution presents itself. It would be well if some druggist prepared it, but a perfectly reliable man would be necessary. Meanwhile I distribute serum whenever I have it, and I keep a little for the purpose of continuing my researches. With best thanks and sincere regards,—Yours,

"April 23rd.

ROGER."

ROME.

(FROM OUR OWN CORRESPONDENT.)

Cerebro-spinal Meningitis.

SOMETHING like a panic pervaded the arsenal of Spezia from the comparatively sudden and widely diffused malaise of a clearly infective character that recently visited the personnel, naval and military. It was at its worst in the Vivera barracks and on board the *Italia*, and before the

medical authorities had time to report upon it a clamour arose in the lay press as to the remissness of the hygiene and the general incompetence of the sanitary and clinical service. Official inquiry has promptly put an end to these charges. There has been neither individual remissness nor general incompetence. The "malaise" in question has turned out to be cerebro-spinal meningitis, a too familiar scourge of the armies and navies of all countries, and its prevalence as well as gravity has been reduced, or rather dwarfed, to quite inconsiderable proportions. Of the combatant force it seems only six were attacked, three of them belonging to the crew of the *Italia* and three to the 93rd Regiment of Infantry quartered in the Vivera barracks. The non-combatant cases were really *une quantité négligeable*. There have been no deaths, and the result of the inquiry has been to confirm once more the established induction that cerebro-spinal meningitis is an infective malady which, *par excellence*, runs an epidemic course from December to June, and is most formidable in the spring; that it is favoured by the assemblage of individuals *en masse*, as in garrisons and on board ship; and that among these it selects the younger recruits, particularly after severe drill or work. Another finding of the official inquiry has been that the *Italia* more than maintains the character of the magnificent Italian iron-clads for hygienic efficiency, and that the Vivera barracks have a quite satisfactory record from a sanitary point of view. I may add that the attempt to prove that the epidemic had been propagated to the civilian population broke down completely, after the special report counter-signed by the Syndic of Spezia, Signor Paita, member of the Chamber of Deputies.

Argon.

One of our ablest physicists, Dr. Massimo Tortelli, has just delivered a lecture, before the Circolo dei Naturalisti, on "Argon e la Chimica dell' Atmosfera," argon being the new atmospheric gas discovered not more than three months ago. Cavendish, he showed, had, before his death in 1810, succeeded in isolating, but not in identifying, this body, owing doubtless to the imperfect means of analysis available at that time. Chemical science, indeed, is full of such partial anticipations—Avogadro's hypothesis, for example, having been so far in advance of his contemporaries that it had fallen into oblivion until, with the discovery of new facts, it was resuscitated and put on a really scientific basis by the present occupant of the Chair of Chemistry in the Roman University, Professor Stanislas Cannizzaro. Dr. Tortelli's lecture, full of incidental matter peculiarly interesting to the medical climatologist, is one of a series which evokes the greatest interest in the profession. The lecture announced for the week following is on the much-debated theme "Il Lavoro Utile dei Microbi nella Società," and will be delivered by Dr. Giuseppe Sanarelli, Professor of Hygiene in the University of Siena.

The Health of the Pope.

The Holy Father, in spite of the fatigues inseparable from Easter-tide, is in good health and eager to get out of doors. Since December last he has not once descended to his favourite Vatican Gardens, where, besides enjoying the incomparable amenity of the walks and parterres and shady tufts and fountains, he always interests himself in watching the cultivators at work and in questioning them as to their progress. The Commendatore Dr. Laponi, however, has postponed this open-air exercise till the weather has become steadier and warmer, the snow still lingering on the Apennines and acting as a refrigerator over all Central Italy.

Dr. Baccelli.

The general elections are imminent, and a strong committee has been for some time at work to secure the return of the Minister of Public Instruction, Dr. Guido Baccelli, who sits for the third division of Rome. There is no doubt of his coming in at the top of the poll, his popularity as a citizen being hardly second to his prestige as a Minister and his distinction as a clinical teacher and consultant.

Professor Karl Posner.

Among the eminent *forestieri* now with us the Professor of Internal Medicine in the University of Berlin has been cordially welcomed at the Accademia Medica di Roma. He has already seen much of our clinical work under the congenial auspices of the President of the Accademia, Dr. Baccelli.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Antitoxin Treatment in Austria and Hungary.

EVER since that memorable meeting of the Vienna Medical Society when Professor Wiederhofer entered the lists against Professor Kassowitz the question of serum treatment has been the order of the day. The medical journals publish articles on both sides, and sometimes new remedies are proposed for diphtheria, hydrogen peroxide for instance. In a report presented at a meeting of the Hungarian Medical Society Professor Purjesz (Klausenburg) accused Dr. Behring of having over-hastily published his remedy, and Dr. Alldi related a case where the prophylactic injection of antitoxin (100 normal units) had caused fatal nephritis in a girl three years old. On the other hand, Dr. Vucetic (*Vienna Medical Journal*) notes the following effects of antitoxin: (1) it has an advantageous influence, and this influence may be accelerated by early injection; (2) the false membranes are more easily loosened; (3) the unfavourable effects for the greater part are dependent upon idiosyncrasy; and (4) the antitoxin treatment is a temporary prophylactic against diphtheria. But between the eulogists and the opponents of antitoxin stand those who follow the old principle: *Medio tutissimus ibis*.

Disintegration of Bodies after Interment.

A lecture on the above subject was recently delivered by Dr. Kratter, Professor of Forensic Medicine at Gratz, at a meeting of the society called "Flame," which advocates the practice of cremation in Austria. The series of changes begins with the distribution of the blood. When the blood is no longer propelled by the action of the heart it sinks to the dependent parts of the body, following the law of gravitation. The vessels soon become unable to resist the blood pressure, and the consequence is that the blood and the fluids of the tissues become extravasated, elevating the epidermis in blisters, which burst and allow all the fluid to escape. This process takes two months. From the complex molecules composing the human body more simple combinations are gradually formed, and in an early stage the albuminates give rise to ptomaines, products resembling vegetable poisons. What we term cadaveric poisoning is not caused by the above-mentioned substances, but by living organisms. Many insects, especially flies, assist in the decomposition of the corpse. When one genus of these perishes a second arrives to continue the work of destruction. First come the muscle destroyers, then the fat destroyers, and finally those that form humus. The soft parts of a full-grown body are decomposed within two years, a space of time which may be prolonged by want of some conditions, such as warmth, moisture, and the access of air. The fluids of the corpse generally suffice to start the decomposition; if they are deficient the bodies turn to mummies, such as have been found in some graves of Germany and Piedmont, whereas abundance of moisture produces adipocere. Seeing that the same oxidation products (CO_2 , HNO_3 , H_2SO_4) occur in the last stage of decomposition as in combustion these processes are to be considered as ultimately identical.

Dermatological Society and Congress.

At the last meeting of this society Dr. Nobel, assistant to Professor Lang, exhibited three cases of Lupus which had been treated by excision and transplantation, the diseased tissues having been removed by dissecting off the entire floor of the ulcers. The wounds healed and the scars resulting from them were not very perceptible. In consequence of these gratifying results Professor Neumann recommended the radical treatment, except in the case of lupus on the ala nasi, where skin grafting and cauterising were more successful. The general secretary of the congress to be held under the auspices of the German Dermatological Society at Gratz on Sept. 23rd, 24th, and 25th has announced that there are two subjects to which special attention will be directed: (1) Pemphigus, introduced by Kaposi (Vienna) and Roentgen (Berlin); and (2) Syphilis, introduced by Neisser (Breslau) and Caspary (Königsberg).

Echinococcus Cyst of the Omentum.

Dr. Frank at a recent meeting of the Vienna Medical Society exhibited an echinococcus cyst remarkable by reason of its position. The patient, a woman twenty-six years of age, suffered from a tense fluctuating tumour, which could be felt

above the symphysis pubis, and was supposed to be cysto-ovarian. The cyst was removed by laparotomy and was found to be of an ovoid form, measuring in its long diameter 17 centimetres ($=6\frac{1}{2}$ inches) and in its transverse diameter 13 centimetres ($=5\frac{1}{4}$ inches). It contained a turbid yellow fluid, the sediment of which consisted of scolices in a state of fatty degeneration, whereas the wall of the cyst was covered with numerous sterile secondary vesicles. In 1892 Professor Albert exhibited a similar case, and the late Professor Billroth explained that cysts of the omentum owed their origin to the bursting of an echinococcus of the liver. In this case no implication of the liver was observed during the operation.

April 22nd.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board in the subjects indicated under the "five" years' regulations, viz:

Part I., Chemistry and Physics:—

Archer, John Alfred, Mason College, Birmingham.
Ashmore, Arthur, Yorkshire College, Leeds.
Barron, Robert Macpherson, Guy's Hospital.
Blatchford, William Nichols, University College, Bristol.
Bradbury, John Cecil Openshaw, Cambridge University.
Brownrigg, Joseph, University College, Liverpool.
Burgess, Percy Charles, Middlesex Hospital.
Carlyon, Arthur Farrington, Middlesex Hospital.
Carr, Henry Brookes, Guy's Hospital.
Charlton, John Fitzgerald, Charing-cross Hospital.
Cook, Lewis, Westminster Hospital.
Cope, Gilbert Edgar, Westminster Hospital.
Daly, Frederick James Purcell, London Hospital.
Driscoll, Louis Cornelius, Charing-cross Hospital.
Dyer, Walter Percy, St. Bartholomew's Hospital.
Gee, Claude Alfred Heath, University College, Bristol.
Harris, Robert James, St. Thomas's Hospital.
Hayes, Arthur Herbert, St. Bartholomew's Hospital.
Hodgson, Robert Edward, St. Mary's Hospital.
Humphreys, Jack Edmund, Charing-cross Hospital.
Johnson, William, Guy's Hospital.
Kirkconnel, Edward Birchall, Owens College, Manchester.
Lamborn, William Alfred, Middlesex Hospital.
Longthorn, Jonathan Harry, Yorkshire College, Leeds.
May, Harry John, London Hospital.
Nunn, John Wilfred, St. Bartholomew's Hospital.
Palmer, William Grimes, Cambridge University and Guy's Hospital.
Perks, Alfred, Guy's Hospital.
Pritchett, George William Morris, University College, London.
Purkis, Dennis Woodley, St. Bartholomew's Hospital.
Rickard, Cecil Rodney, Middlesex Hospital.
Sanders, James Herbert, London Hospital.
Sells, Charles Bernard, Guy's Hospital.
Shoosmith, Louis Stephen, St. Mary's Hospital.
Speers, William Gordon, St. Mary's Hospital.
Stevens, Stanley, St. Bartholomew's Hospital.
Stratford, Howard Blenheim Martin, Oxford University.
Thomas, Harold Sebert, St. Bartholomew's Hospital.
Thwaites, Henry, London Hospital.
Tongue, George Preston, St. Paul's School, West Kensington.
Ward, Percy Harold, Guy's Hospital.
Wood, Charles Herbert, University College, London.
Wright, Thomas James, Guy's Hospital.

Part II., Practical Pharmacy:—

Allen, Walter Francis, London Hospital.
Bryan, Clement Arthur Douglas, Guy's Hospital.
Deas, Percival Bruce, St. Mary's Hospital.
Erlinger, Frederick Kinard, University College, London.
Francis, William Vere Chalmer, Westminster Hospital.
Griffith, John Richard, London Hospital.
Holmes, Willmot, St. Mary's Hospital.
Oxley, James Charles Stewart, St. Thomas's Hospital.
Pocock, Arthur Robert George, University College, London.
Sherren, James, London Hospital.
Williams, Eric Wadlow, St. Mary's Hospital.

Part III., Elementary Biology:—

Asten, Walter, Mason College, Birmingham.
Atkinson, George James Smith, St. Paul's School, West Kensington.
Bagshawe, Herbert Vale, Guy's Hospital.
Baker, Dodington George Richard S., University College, London.
Baker, William Lincoln, St. Mary's Hospital.
Barlow, Edward Hovenden, Guy's Hospital.
Bartlett, Ernest John Reeve, King's College, London.
Bartlett, Basil Sorley, University College, London.
Beard, Joseph, Firth College, Sheffield.
Bell, John Cunningham, University College, London.
Bennett, William Frederick C., Firth College, Sheffield.
Betts, Alfred John Vernon, Westminster Hospital.
Biggs, Reginald, St. Bartholomew's Hospital.
Black, Guy, St. Thomas's Hospital.
Blake, Percy Ryall, London Hospital.
Bolman, Christopher Osmond, University College, Bristol.
Boursot, Basil John, St. Bartholomew's Hospital.

Brown, Thomas Walker Stanley, Guy's Hospital.
 Brown, Thomas Warren, St. Bartholomew's Hospital.
 Butler, Harold Branson, St. Bartholomew's Hospital.
 Carter, Robert Markham, St. George's Hospital.
 Cathcart, George Elliott, St. Bartholomew's Hospital.
 Causton, Albert Edward, Guy's Hospital.
 Clarke, Edward Murray, University College, Cardiff.
 Cocke, Robert Sturgeon, King's College, London.
 Compton, Maurice Winzar, St. Thomas's Hospital.
 Compton, Spencer Langley, University College, Bristol.
 Cook, Lewis, Westminster Hospital.
 Cooke, Reginald Torriano, St. Bartholomew's Hospital.
 Cooper, Walter Edward, University College, London.
 Corbett, Sidney D'Alton, St. George's Hospital.
 Cornish, Charles Vivian, St. Bartholomew's Hospital.
 Cornish, Phillip Alfred, Middlesex Hospital.
 Crawley, Herbert Edward, Oxford University.
 Crompton, Richard Henry, University College, Liverpool.
 Davies, Daniel, St. Bartholomew's Hospital.
 Dismore, Henry Bertram, Guy's Hospital.
 Dodd, Stanley, Westminster Hospital.
 Douglass, William Claughton, St. Bartholomew's Hospital.
 Dowman, Charles Darby Allen, St. Bartholomew's Hospital.
 Dudding, John Scarbrough, London Hospital.
 Dudgeon, Leonard Stanley, St. Thomas's Hospital.
 Durand, William Arthur, Westminster Hospital.
 Edington, Ernest Adolphus, University College, London.
 Edmonds, Charles John Ernest, St. Thomas's Hospital.
 Edwards, Charles, Guy's Hospital.
 Edwards, David Richard, University College, Cardiff.
 Ekins, Charles Maxwell, University College, London.
 Esser, Samuel Jonathan David, London Hospital.
 Evans, Arthur John, University College, London.
 Evans, Sydney James, Guy's Hospital.
 Everington, Francis Edgar, St. Bartholomew's Hospital.
 Facey, Reginald Ambrose, St. Mary's Hospital.
 Farquharson, Charles Henry, St. Mary's Hospital.
 Fawcett, Basil, St. Thomas's Hospital.
 Fenton, Thomas Gerald, St. Thomas's Hospital.
 Flewitt, Charles York, Mason College, Birmingham.
 Flint, Harold Edwards, St. Bartholomew's Hospital.
 Forbes, Cyril Donald Edward, St. George's Hospital.
 Forrest, Bertie Thomas, St. Thomas's Hospital.
 Francis, James Bernard Chalmers, Westminster Hospital.
 Fyfe, Robert James, Firth College, Sheffield.
 Goble, Edwin Wallace, Guy's Hospital.
 Gould, Reginald, London Hospital.
 Graham, William Earnest, St. Bartholomew's Hospital.
 Greaves, Herbert Stanley, St. Bartholomew's Hospital.
 Green, Samuel Morris, University College, Liverpool.
 Grenfell, Pascoe Beville, St. Bartholomew's Hospital.
 Gubbins, John Gaspard, St. Thomas's Hospital.
 Haig, Thomas Baker, St. Bartholomew's Hospital.
 Halliday, John Rutherford, London Hospital.
 Hamilton, William Gavin, St. Bartholomew's Hospital.
 Hammeton, George Herbert Leonard, Firth College, Sheffield.
 Hartley, John Dawson, St. Bartholomew's Hospital.
 Harvey, Joseph Frederick, Mason College, Birmingham.
 Hawkes, Alfred Ernest Underwood, University College, Liverpool.
 Hearn, Edward Michael William, London Hospital.
 Hearn, Ethelbert, Firth College, Sheffield.
 Hemstead, Henry, University College, Bristol.
 Herklots, Gerald Andreas, University College, London.
 Hicks, Charles Edward, Guy's Hospital.
 Higson, Thomas, Owens College, Manchester.
 Hobbs, Albert Remington, St. Mary's Hospital.
 Hollicks, Hubert Harry, Mason College, Birmingham.
 Holmes, Willmot, St. Mary's Hospital.
 Hope, Walter Bayard, Guy's Hospital.
 Horsburgh, Charles Bethune, University College, Bristol.
 Hubert, Edgar Hamilton, St. George's Hospital.
 Humby, Harry Robinson, St. Bartholomew's Hospital.
 Humby, John Daniel Dawson, St. Bartholomew's Hospital.
 Hunt, John William, St. Mary's Hospital.
 James, Frederick William, University College, London.
 Jefferriss, Iain McKinnon, King's College, London.
 Jones, Bertrand Seymour, St. Thomas's Hospital.
 Kelly, Thomas Thelwell, Guy's Hospital.
 Kerfoot, Stanley James, London Hospital.
 Lamb, Ralph, University College, Liverpool.
 Leclézio, George Joseph Alexis, St. Bartholomew's Hospital.
 Lee, Charles, Firth College, Sheffield, and Guy's Hospital.
 Leonard, William Hugh, St. Bartholomew's Hospital.
 Lewis, Ivor Cadwaladr, St. Bartholomew's Hospital.
 Loosely, William Henry, Guy's Hospital.
 McClintock, John, King's College, London.
 McLachlan, Arthur Ronald, Guy's Hospital.
 Mason, Herbert Alfred, Firth College, Sheffield.
 Mayne, William Boxer, University College, London.
 Miller, John, Owens College, Manchester.
 Mitchell, Edward Percival, Guy's Hospital.
 Muir, Berthold, Guy's Hospital.
 Neave, Sheffield, St. Bartholomew's Hospital.
 Oates, James Christopher, Mason College, Birmingham.
 O'Hea, John, St. Bartholomew's Hospital.
 Olvey, John Michael Abraham, St. Thomas's Hospital.
 Parsons, Ernest Alsager, Mason College, Birmingham.
 Perks, John, St. Bartholomew's Hospital.
 Pinches, Horace George, St. Thomas's Hospital.
 Pinker, Henry George, St. Bartholomew's Hospital.
 Pomeroy-Trood, Scobell, St. Bartholomew's Hospital.
 Price, Edwin Edgar Montague, Mason College, Birmingham.
 Price, Sydney Edgar, Mason College, Birmingham.
 Prichard, John Llewelyn, University College, Liverpool.
 Prins, Henry Mallock, University College, London.
 Pugh, Arthur Bailey, St. Bartholomew's Hospital.
 Randolph, William Henry, St. Bartholomew's Hospital.
 Rodil, Juan José, Guy's Hospital.

Rogers, Frederick Colin, St. Mary's Hospital.
 Rowland, Frank, Mason College, Birmingham.
 Sanders, Edward Arthur, King's College, London.
 Scorch, Ernest John, Firth College, Sheffield.
 Scott, Edward Fletcher, Guy's Hospital.
 Shelton, Arthur Izod, University College, London.
 Shorland, George, Guy's Hospital.
 Simpson, Graham Seales, Guy's Hospital.
 Smith, Alan Ayre, Guy's Hospital.
 Smith, Leonard Satchwell, Mason College, Birmingham.
 Smith, Sydney, University College, London.
 Smith, Thomas Shalden, St. Mary's Hospital.
 Smith, Thomas William, Charing-cross Hospital.
 Softly, Alfred Ernest, St. Thomas's Hospital.
 Speirs, William Clark, St. Mary's Hospital.
 Stephens, Henry Zouch, St. Thomas's Hospital.
 Sykes, Walter, Owens College, Manchester.
 Takaki, Yashihiko, St. Thomas's Hospital.
 Talbot, Ashby West, Guy's Hospital.
 Thomas, Alfred Messer, Guy's Hospital and Durham University.
 Thomas, William Murray, Guy's Hospital.
 Thompson, Cecil Charles Brandon, St. Bartholomew's Hospital.
 Thompson, Henry Bates, Mason College, Birmingham.
 Thornley, Robert Lewis, St. Bartholomew's Hospital.
 Tredgold, Alfred Frank, London Hospital.
 Twaot, Frederick William, St. Thomas's Hospital.
 Velenski, John Charles, London Hospital.
 Vickers, Thomas Hedley, St. Mary's Hospital.
 Vincent, Ralph Harry, St. Bartholomew's Hospital.
 Visger, Charles, University College, London.
 Wakefield, Walter, Mason College, Birmingham.
 Walker, Robert, St. Bartholomew's Hospital.
 Waters, James, Middlesex Hospital.
 West, John Arthur, St. Bartholomew's Hospital.
 Ward, Oswald Erasmus, Mason College, Birmingham.
 Weston, Herbert Ernest, St. George's Hospital.
 Wethered, Ernest, St. Bartholomew's Hospital.
 White, Cyril Charles Coleby Kirke, St. Bartholomew's Hospital.
 Wilkinson, Edgar Sheldon, St. Bartholomew's Hospital.
 Williams, Eric Wadlow, St. Mary's Hospital.
 Wilson, Hugh Cameron, St. Mary's Hospital.
 Winterbotham, Rayner, University College, London.
 Woodforde, Robert E. Heighes, St. Bartholomew's Hospital.
 Woodhill, Henry Gilbert, St. Bartholomew's Hospital.
 Wright, Thomas James, Guy's Hospital.

Part IV., Elementary Anatomy :—

Acland, Hugh Thomas Dyke, St. Thomas's Hospital.
 Agate, Henry St. Annaud, St. Mary's Hospital.
 Alderson, Percy Francis, Middlesex Hospital.
 Allen, Walter Francis, London Hospital.
 Anley, Frederick Eustace, Charing-cross Hospital.
 Atkins, John, Guy's Hospital.
 Aubrey, Thomas, University College, Bristol.
 Austin, Elfred Chalmers, St. Mary's Hospital.
 Bagshawe, Herbert Vale, Guy's Hospital.
 Baker, Arthur Russell, St. Bartholomew's Hospital.
 Baker, William Lincoln, St. Mary's Hospital.
 Barlow, Edward Hovenden, Guy's Hospital.
 Barnes, Arthur Stanley, Mason College, Birmingham.
 Bartlett, Ernest John Reeve, King's College, London.
 Bastian, William, University College, London.
 Baxter, Charles Thomas, Middlesex Hospital.
 Beale, Hanway Richard, St. Thomas's Hospital.
 Beard, Joseph, Firth College, Sheffield.
 Beaumont, Noel Charles, St. Bartholomew's Hospital.
 Bell, John Cunningham, University College, London.
 Bennett, Charles Harold, St. Mary's Hospital.
 Bennett, William Frederick Cockayne, Firth College, Sheffield.
 Bevan, Arthur, St. Thomas's Hospital.
 Black, Guy, St. Thomas's Hospital.
 Blake, Frederick James Guy, Yorkshire College, Leeds.
 Blake, Percy Ryall, London Hospital.
 Bostman, Christopher Osmond, University College, Bristol.
 Borrow, Frederick Charles, St. Bartholomew's Hospital.
 Bourdas, Ernest Clarkson, St. Thomas's Hospital.
 Brockwell, John Brocas Chambers, Guy's Hospital.
 Brook, Francis William, Guy's Hospital.
 Brown, Alexander, King's College, London.
 Browne, Thomas Walker Stanley, Guy's Hospital.
 Bryan, Clement Arthur Douglas, Guy's Hospital.
 Bullen, Edward Henry, St. Mary's Hospital.
 Burgess, Percy Charles, Middlesex Hospital.
 Burrows, Harold, St. Bartholomew's Hospital.
 Calvert, Hubert, St. Thomas's Hospital.
 Carter, Robert Markham, St. George's Hospital.
 Causton, Albert Edward, Guy's Hospital.
 Chapman, Donald Poyntez, Charing-cross Hospital.
 Chetwood, Thomas, London Hospital.
 Clarke, Edward Murray, University College, Cardiff.
 Clarke, Henry Hugh Rose, St. Thomas's Hospital.
 Coleman, Frank, Charing-cross Hospital.
 Coleridge, Alfred, University College, Bristol.
 Collins, John Moore, St. Bartholomew's Hospital.
 Compton, Spencer Langley, University College, Bristol.
 Cook, Lewis, Westminster Hospital.
 Cooke, Reginald Torriano, St. Bartholomew's Hospital.
 Cooper, Walter Edward, University College, London.
 Cope, Gilbert Edgar, Westminster Hospital.
 Corbet, Sidney D'Alton, St. George's Hospital.
 Cornish, Charles Vivian, St. Bartholomew's Hospital.
 Cornish, Phillip Alfred, Middlesex Hospital.
 Cunningham, John Francis, St. Thomas's Hospital.
 D'Aguilar, John Burton Stockwell, University College, Bristol.
 Danks, Walter Seymour, St. Bartholomew's Hospital.
 Davey, John Bernard, Middlesex Hospital.

Davis, Alexander Montague, Mason College, Birmingham.
 Davies, Arthur Gerald Capel, Guy's Hospital.
 Davies, Daniel, St. Bartholomew's Hospital.
 Davies, Enoch Howell, University College, Cardiff.
 Deas, I. cervical Bruce, St. Mary's Hospital.
 Denny, Herbert Reginald Harry, Guy's Hospital.
 Densham, Alec, Guy's Hospital.
 Dick, Walter, University College, London.
 Dismorr, Harry Bertram, Guy's Hospital.
 Dodd, Stanley, Westminster Hospital.
 Double, Meredith Sedgwick, Charing Cross Hospital.
 Drake-Brockman, Henry George, St. George's Hospital.
 Dudding, John Scarbrough, London Hospital.
 Dudgeon, Leonard Stanley, St. Thomas's Hospital.
 Dunstan, Walter Robert, London Hospital.
 Edington, Ernest Adolphus, University College, London.
 Edmunds, Charles John Ernest, St. Thomas's Hospital.
 Edwards, David Richard, University College, Cardiff.
 Elwes, Frederick Fenn, Middlesex Hospital.
 Evans, Arthur John, University College, London.
 Evans, Sydney James, Guy's Hospital.
 Farquharson, Charles Henry, St. Mary's Hospital.
 Fawcett, Basil, St. Thomas's Hospital.
 Fenton, Thomas Gerald, St. Thomas's Hospital.
 Flewitt, Charles York, Mason College, Birmingham.
 Foster, Henry Bertram, Guy's Hospital.
 Fowler, Edwin Samuel George, Yorkshire College, Leeds.
 Frear, Alexander, St. Mary's Hospital.
 Frost, Cecil Scarlett, St. Bartholomew's Hospital.
 Frost, Joseph Reginald, University College, Bristol.
 Fyffe, Robert James, Firth College, Sheffield.
 Gaff, James, St. Thomas's Hospital.
 Gandy, Thomas Hall, St. Bartholomew's Hospital.
 Gee, Claude Alfred Heath, University College, Bristol.
 Goble, Edwin Wallace, Guy's Hospital.
 Goode, George Ernest, London Hospital.
 Goodman, Harold, St. Bartholomew's Hospital.
 Goodwin, William Richard Power, St. Mary's Hospital.
 Graham, William Ernest, St. Bartholomew's Hospital.
 Greaves, Herbert Stanley, St. Bartholomew's Hospital.
 Grenfell, Pascoe Beville, St. Bartholomew's Hospital.
 Gribbell, William Ernest, St. Mary's Hospital.
 Gubbins, John Gaspard, St. Thomas's Hospital.
 Haig, Thomas Baker, St. Bartholomew's Hospital.
 Harris, Herbert Stocker, St. Thomas's Hospital.
 Hartley, John Dawson, St. Bartholomew's Hospital.
 Harvey, Joseph Frederick, Mason College, Birmingham.
 Hawes, Colin Sadler, St. Bartholomew's Hospital.
 Hawker, Herbert, University College, London.
 Haydon, William Chatterley, St. Mary's Hospital.
 Hearn, Edward Michael, London Hospital.
 Heath, Philip Maynard, University College, London.
 Higgins, Hugh Arthur, Guy's Hospital.
 Higson, Thomas, Owens College, Manchester.
 Hodgson, Harold West, London Hospital.
 Hodgson, Robert Edward, St. Mary's Hospital.
 Hollick, Hubert Harry, Mason College, Birmingham.
 Horsburgh, Charles Bethune, University College, Bristol.
 Horton, Horatio Nelson, Middlesex Hospital.
 Hubert, Edgar Hamilton, St. George's Hospital.
 Hughes, Frank Percival, University College, Bristol.
 Hunt, John William, St. Mary's Hospital.
 Ingram, Percy Cecil Parker, University College, Cardiff.
 Inman, William Sam, Firth College, Sheffield.
 James, Charles Willmot Wanklyn, University College, Bristol.
 James, Frederick William, University College, London.
 Jeaffreson, Dudley, St. Bartholomew's Hospital.
 Jefferiss, Frederick Burroughs, King's College, London.
 Jefferiss, Iain Mackinnon, King's College, London.
 Jones, Arthur Webb, St. Thomas's Hospital.
 Jones, Bertrand Seymour, St. Thomas's Hospital.
 Lamb, Ralph, University College, Liverpool.
 Lamborn, William Alfred, Middlesex Hospital.
 Lees, Charlie, Charing-cross Hospital.
 Leggatt, Claude Edward Heisch, St. Mary's Hospital.
 Leonard, William Hugh, St. Bartholomew's Hospital.
 Lewis, Ivor Cadwaladr, St. Bartholomew's Hospital.
 Lewis, William Edward Vaughan, Mason College, Birmingham.
 Lilley, Ernest Lewis, Charing Cross Hospital.
 Loosely, William Henry, Guy's Hospital.
 Low, George Harvey, St. Bartholomew's Hospital.
 McEnery, Ambrose Richard, University College, Bristol.
 McMullen, William Halliburton, King's College, London.
 Mason, Herbert Alfred, Firth College, Sheffield.
 Mayne, William Boxer, University College, London.
 Meredith, Richard William Herbert, Middlesex Hospital.
 Merry, Edward, London Hospital.
 Miller, John, Owens College, Manchester.
 Mitchell, Edward Percival, Guy's Hospital.
 Morgan, John David, St. Mary's Hospital.
 Morley, Arthur Solomon, St. George's Hospital.
 Morris, Herbert Edward, Guy's Hospital.
 Moss, Bertram Wilmore, Guy's Hospital.
 Muir Berthold, Guy's Hospital.
 Munro, Donald John, Guy's Hospital.
 Muter, Charles William, King's College, London.
 Neave, Sheffield, St. Bartholomew's Hospital.
 New, John Sherwood, University College, London.
 Nicholls, Percival Thomas, Middlesex Hospital.
 Nitch, Cyril Alfred Rankin, St. Thomas's Hospital.
 Nutt, Harold Rothery, St. Mary's Hospital.
 Oates, James Christopher, Mason College, Birmingham.
 O'Hea, John, St. Bartholomew's Hospital.
 Olivey, John Michael Abraham, St. Thomas's Hospital.
 Orford, Herbert John, Mason College, Birmingham.
 Osborn, Alfred Gelsthorpe, Guy's Hospital.
 Parsons, Ernest Alsager, Mason College, Birmingham.
 Passmore, William Henry, Charing Cross Hospital.
 Paul, John Frederick, St. George's Hospital.

Peach, William Frank, St. Mary's Hospital.
 Peck, William Edward, University College, London.
 Peirce, Thomas James, St. George's Hospital.
 Perrin, Thomas, St. Thomas's Hospital.
 Pinches, Horace George, St. Thomas's Hospital.
 Pollard, Herbert Dean, London Hospital.
 Pooley, John Milnes, St. Mary's Hospital.
 Pretty, Harold Cooper, University College, London.
 Price, Edwin Edgar Montague, Mason College, Birmingham.
 Price, Sydney Edgar, Mason College, Birmingham.
 Pring, Charles Herbert, University College, Bristol.
 Prins, Henry Mallock, University College, London.
 Pugh, Arthur Bailey, St. Bartholomew's Hospital.
 Randolph, William Henry, St. Bartholomew's Hospital.
 Ransford, Alan Carpmal, Guy's Hospital.
 Reeve, Herbert Midgley, Guy's Hospital.
 Reid, Archibald Douglas, King's College, London.
 Rodil, Juan José, Guy's Hospital.
 Rogers, Frederick Colin, St. Mary's Hospital.
 Rowland, Frank, Mason College, Birmingham.
 Russell-Risien, Ernest, St. Bartholomew's Hospital.
 Rutter, Thomas Francis, Guy's Hospital.
 Sanders, Edward Arthur, King's College, London.
 Sanders, James Herbert, London Hospital.
 Scorch, Ernest John, Firth College, Sheffield.
 Scott, Edward Fletcher, Guy's Hospital.
 Scott, Sydney Richard, St. Bartholomew's Hospital.
 Scott, Henry Martin, Charing-cross Hospital.
 Serase, James John Sheat, St. Bartholomew's Hospital.
 Secretan, Walter Bernard, Guy's Hospital.
 Segreda, Francisco Arturo, Guy's Hospital.
 Sells, Lionel, St. Thomas's Hospital.
 Sheehan, Michael, Queen's College, Cork.
 Sheldon, Arthur Izod, University College, London.
 Sherren, James, London Hospital.
 Simpson, Graham Scales, Guy's Hospital.
 Simpson, John Edgar, University College, London.
 Smith, Alan Ayr, Guy's Hospital.
 Smith, Percy Nelson, St. Mary's Hospital.
 Smith, Sydney, University College, London.
 Smith, Thomas Shalden, St. Mary's Hospital.
 Softly, Alfred Ernest, St. Thomas's Hospital.
 Speers, William Gordon, St. Mary's Hospital.
 Speirs, George Benjamin Arnes, St. Mary's Hospital.
 Sprague, Francis Henry, St. Mary's Hospital.
 Sprawson, Cuthbert Allan, King's College, London.
 Staines, Tom Fenn, King's College, London.
 Stanley, Edmund Hamilton Blake, University College, London.
 Stephens, Henry Zouch, St. Thomas's Hospital.
 Stevens, Stanley, St. Bartholomew's Hospital.
 Stevens, Warwick Alan George, Guy's Hospital.
 Stewart, Walter Graham, Guy's Hospital.
 Stock, Philip Graham, University College, Bristol.
 Stokes, Percy Southwall, Firth College, Sheffield.
 Stratford, Howard Martin Blenheim, Oxford University.
 Swan, Russell Henry Jocelyn, Guy's Hospital.
 Takaki, Yoshihiro, St. Thomas's Hospital.
 Tallot, Ashley West, Guy's Hospital.
 Taylor, Henry Christopher, St. Mary's Hospital.
 Thomas, Harold Sebert, St. Bartholomew's Hospital.
 Thomas, William Murray, Guy's Hospital.
 Thompson, Joseph Bernard, University College, London.
 Townroe, Eugene Dunbar, St. George's Hospital.
 Tredgold, Alfred Frank, London Hospital.
 Truman, Dudley Beckett, King's College, London.
 Trumper, William Arthur, St. Mary's Hospital.
 Turner, Frank Douglas, Guy's Hospital.
 Twort, Frederick William, St. Thomas's Hospital.
 Vaughan, Arthur Llewellyn, St. Bartholomew's Hospital.
 Vawdrey, Percy Llewellyn, St. Bartholomew's Hospital.
 Velenski, John Charles, London Hospital.
 Vickers, Thomas Hedley, St. Mary's Hospital.
 Vine, Alfred Bertram, Middlesex Hospital.
 Visger, Charles, University College, London.
 Von Rosen, Alfred Dittlof Benedictus, St. Mary's Hospital.
 Walker, Lewis Augustus, St. Bartholomew's Hospital.
 Ward, Oswald Erasmus, Mason College, Birmingham.
 Waters, James, Middlesex Hospital.
 Waters, Walter James, St. Thomas's Hospital.
 Watson, Robert Nimmo, Westminster Hospital.
 Wells, Albert John Walton, St. Bartholomew's Hospital.
 Wells, Hardy Vesey, St. Mary's Hospital.
 Weston, Alfred Fullam, St. George's Hospital.
 Wethered, Ernest, St. Bartholomew's Hospital.
 White, Charles Vaughan, St. Thomas's Hospital.
 White, Cyril Charles, Coleby Kirke, St. Bartholomew's Hospital.
 White, Percy Walter, University College, Bristol.
 Wilkes, Alfred Ernest Frear, Mason College, Birmingham.
 Williams, Eric Wadlow, St. Mary's Hospital.
 Williams, Sydney Bice, University College, Bristol.
 Winterbotham, Rayner, University College, London.
 Woodcock, Henry Chadwick, St. Mary's Hospital.
 Wood-Hill, Henry Gilbert, St. Bartholomew's Hospital.
 Wright, Thomas James, Guy's Hospital.

SOCIETY OF APOTHECARIES OF LONDON. — The following gentlemen were admitted Licentiates in April:—

J. MacD. Troup, W. H. Daw, T. H. Hunt, J. H. P. Vivian, and A. H. Trevor.

The following candidates have passed in the subjects indicated:—

Surgery.—W. Allen, Birmingham; W. H. Daw, London Hospital; F. W. Gale, St. Bartholomew's Hospital; J. Hepple, Leeds; T. H. Hunt, Leeds; T. H. P. Peers, Charing-cross Hospital; G. R. Smith, Manchester.

Melicine, Forensic Medicine, and Midwifery.—C. N. Barton, St. George's Hospital; W. H. Daw, London Hospital; B. Heiden,

Guy's Hospital: T. H. Hunt, Leeds; A. S. Lawrence, Middlesex Hospital; J. M. Troup, King's College.
Medicine and Forensic Medicine.—G. P. Y. Hulbert, Birmingham and Charing-cross Hospital; J. H. P. Vivian, St. Thomas's Hospital.
Medicine and Midwifery.—J. Hepple, Leeds; and E. P. Hewitt, St. Mary's Hospital.
Medicine.—H. G. Jones, St. Mary's Hospital; and W. McCall, Charing-cross Hospital.
Forensic Medicine.—J. W. F. Graham, St. Bartholomew's Hospital; and A. H. Trevor, Guy's Hospital.

EDINBURGH UNIVERSITY.—The following gentlemen have received the under-mentioned degrees:—

Bachelor of Medicine and Master in Surgery.—James Andrew Gibson; Thomas Smith.

Bachelor of Science.—George Waterston Miller; William Morrison, M.B., C.M.; James Alexander Murray.*

* Passed with special distinction in zoology and comparative anatomy.

FOREIGN UNIVERSITY INTELLIGENCE.—*Vienna*: Dr. Max Herz and Dr. Franz Chrostek have been recognised as *privat-docents* in Medical Pathology.

VACCINATION GRANT.—Mr. Philip Edward Hill, M.R.C.S., public vaccinator for the No. 1 district of the Crickhowell Union, has been awarded, for the ninth time in succession, the Government grant for efficient vaccination.

CENTENARY OF THE ABERNETHIAN SOCIETY.—A conversation in commemoration of the centenary of the Abernethian Society will be held at St. Bartholomew's Hospital on May 1st. Former St. Bartholomew's men will welcome this opportunity of meeting the friends of earlier days, and will find that exceptionally effective arrangements have been made for the evening's entertainment. The History of the Abernethian Society will form the subject of an address by Dr. Norman Moore. Messrs. F. A. Smith and T. Ashby Barron are the honorary secretaries.

THE NEED FOR PUBLIC SLAUGHTER-HOUSES.—At a meeting of the Church Sanitary Association, held at the Church House, Westminster, on Tuesday last, under the presidency of Dr. Norman Kerr, a paper contributed by Dr. Francis W. Clark, medical officer of health, Lowestoft, on "The Need for Public Slaughter-houses" was read by the Rev. Canon Reith. The writer of the paper said there were numerous Acts designed to prevent the adulteration of food, but the motive of these had been, for the most part, the purely commercial one of depreciated value, and not the hygienic one of wholesomeness. The cocoa and vinegar sold by the grocer were sampled, and penalties inflicted if they were not pure; but when it came to our meat supplies people were content to purchase anything provided only that "it looked all right." Few sanitary authorities had seen the wisdom of providing for the due and proper slaughtering and the adequate inspection of all animals for human food, and a lesson might well be learnt from our Continental neighbours, who were far ahead of us in this respect. The slaughtering of animals for food was an operation which must necessarily be attended by a certain amount of nuisance and danger to the health of those in the immediate vicinity, unless it was carried out with the most ample sanitary conveniences and appliances, and therefore the English system of private slaughter-houses must be fraught with danger to the public health. The stabling of cattle, sheep, and pigs in the actual slaughter-house itself were among the least of the defects of these private slaughter-houses, while overcrowding, deficiency of light and of ventilation were to be found in almost all of them. The greatest danger, however, of the English system of slaughtering arose from the failure to detect and destroy all diseased and unwholesome carcasses, and as a consequence much flesh was constantly offered for sale, especially in the poorer quarters, which was unfit for human food. It was unquestionable that tubercle could be conveyed to man by the ingestion of the flesh of tuberculous cattle, and it was an admitted fact that an appreciable proportion of English cattle were tuberculous. One of the most important factors in the prevalence of consumption throughout England was the unrestricted use of milk from tuberculous cows and the eating of imperfectly cooked tuberculous beef. The public must be taught that they cannot estimate the quality of meat by a mere casual inspection, and he hoped that the Church Sanitary Association and the clergy generally would try to rouse public opinion to a truer recognition of the value of sound and wholesome food. After some remarks from the Chairman, Canon Reith, the Rev. M. C. F. Morris, and the Rev. E. C. C. Parr, the proceedings closed.

MEDICAL MAGISTRATE.—Dr. James Smith Watson of Blackburn has been placed on the Commission to the Peace for that borough.

The festival dinner of the Royal Hospital for Children and Women, Waterloo Bridge-road, S.E., will be held at the Whitehall Rooms, Hôtel Métropole, on Saturday evening, May 4th, 1895, at 7 P.M. The Hon. W. F. Danvers Smith, M.P., will preside.

FOOTBALL CASUALTIES.—On the 13th inst., during a match on the Chanonry grounds between the Aberdeen and Clachnacuddin teams, a player fractured his left clavicle.—At Redruth on Saturday last in a match between the Cornwall and Redruth teams a home forward badly fractured his leg.

ROYAL BRITISH NURSES' ASSOCIATION.—The last sessional lecture of the season was delivered at 17, Old Cavendish-street on Friday, April 19th, before an appreciative audience by Miss Annesley Kenealey, the subject being *Women as Lecturers*. The chair was taken at 8 P.M. by Dr. C. Gage Brown, C.M.G. A discussion took place at the conclusion of the lecture.

DR. G. A. W. WATSON, assistant to Dr. Briscoe, met with a fatal accident at Chippenham. He had been attending a patient at Spire View, London-road, and on coming out attempted to mount his horse, but the animal reared and threw him. Mr. Wilson was first on the scene, and subsequently Dr. Briscoe arrived, but despite every care Dr. Watson never regained consciousness and passed away. He came from Strichen, Aberdeen, and was an M.A. and M.B. of Aberdeen University.

PATHOLOGICAL DEPARTMENT, UNIVERSITY COLLEGE, LIVERPOOL.—Owing to the liberality of Mr. George Holt, the founder of the chair, the department of Pathology and Bacteriology at University College, Liverpool, has been provided with temporary accommodation in Ashton Hall, a house adjoining the College, which has been purchased and most efficiently equipped for the purpose. The apparatus and fittings necessary for teaching and private research are very complete. The new institute is now ready for occupation and will be formally opened at the beginning of the summer session. It consists of three floors, containing separate laboratories for the study of morbid anatomy and histology, bacteriology, experimental and chemical pathology and research. In addition there are photographic rooms, balance room, library, students' rooms, workshop, stable accommodation, and lodges for attendants.

ÆSCULAPIUS LODGE OF FREEMASONS.—The last meeting of this lodge for the present Masonic year was held at the Café Royal, Regent-street, on the 10th inst. There were a large number of members and some visitors present. G. Crawford Thomson, M.D., was unanimously elected Master for the ensuing year, and J. Pickett, M.D., treasurer. In consequence of Dr. G. Danford Thomas having been offered a warden's chair he was not again a candidate for the office of treasurer, which office he has so ably filled for four years. Thomas Dutton, M.D., M.R.C.P. Edin., was reappointed secretary; Leonard Wilde, M.D., M.R.C.P. Lond., was admitted to the third degree; and George Herschell, M.D. Lond., M.R.C.S. Eng., was admitted into Freemasonry. T. H. Openshaw, M.B., F.R.C.S. Eng., was proposed as a joining member. Two guineas out of the charity fund were voted for Mr. C. Bryan Townshend's case, and 3 guineas for a widow of a medical Mason; £3 10s. was collected for the late Brother Surgeon-Major Parke's Memorial Fund, 2 guineas being previously voted by the lodge. The secretary reported that he had already received the names of most of the medical Grand Officers as patrons in support of the smoking concert, to be given at the Portman Rooms, to all medical Masons who may visit London during the meeting of the British Medical Association. The lodge was then closed; the brethren afterwards dined together.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Easter Recess.

THE House of Commons brought its holiday to a close on Monday, April 22nd. The House of Lords met on the same day, but only for formal business, and adjourned again until Tuesday, April 30th.

The Bovine Tuberculosis Commission.

The report of this Commission has at last been presented to Parliament. It was laid on the table in manuscript on April 22nd, and is now being printed with a view to publication.

The Age Limit in Factories and Workshops.

Sir John Gorst, in anticipation of the committee stage of the Factories and Workshops Bill, has given notice of his intention to move the insertion of a clause to the effect that no child under the age of twelve years shall be employed in a factory or workshop. The present limit is eleven years.

Health Arrangements in Prisons.

In the report of the Departmental Committee on Prisons a section is devoted to the subject of health. The Committee refer to the common assertion that not only is the ratio of insanity far higher in prisons than among the general population, but that prison life itself is a potent cause in its development, and they arrive at certain general conclusions. They think that an early opportunity should be taken of appointing an additional member of the Prisons Board, who should be a medical man, the new office taking the place of the present medical inspectorship. They point out that detection of disease in its earliest stage taxes the skill of the practitioner to its fullest extent, and that in mental diseases this is especially the case. Here medical men of great skill and experience, but without any special training in this department of their art, are undoubtedly at a disadvantage. It appears to the Committee, therefore, that it might with advantage be made a condition of medical appointments in prisons that the candidate should produce evidence of having given special attention to the subject of lunacy. In Belgium the services of physicians specially conversant with mental disorders are retained for the purpose of detecting cases of incipient insanity which might have escaped a less practised eye, and the Committee think that some step of this kind might perhaps be taken, especially with a view of inspecting convicts during their period of isolation. Later the Committee say that in some of the larger prisons it appears to them that the work incumbent on the medical staff is such as to render it very difficult for them to give the detailed and prolonged attention to individual cases which alone can secure the sifting out of such as require special treatment. On the curative and preventive effects of outdoor exercise and labour the Committee state that their medical witnesses were practically unanimous. There are undoubted obstacles to this in the limited space which surrounds most prisons and in the fact that the supervision of prisoners in the open air necessitates some increase in the staff of wardens. Nevertheless the Committee regard the object in view as so important as to justify great efforts and some expense with the view of effecting it so far as may be practicable. With regard to weak-minded prisoners the Committee recommend that they should be concentrated so far as is possible in special prisons and put under special medical supervision, and that it should be considered whether it is right to treat such persons as ordinary criminals.

HOUSE OF COMMONS.

MONDAY, APRIL 22ND.

Sea Squalls and Loss of Life.

In the course of a question addressed to the Board of Trade, Mr. Harry S. Foster called attention to a letter written by the coxswains of the Walmer and Deal lifeboats, stating that in their experience it was very difficult to distinguish at times what was required when they saw signals fired at sea, and that on several occasions they had launched their boats at the risk of their lives in answer to signals supposed to be distress signals, only to find that the vessels firing them did not require assistance.—Mr. Burt, replying on behalf of the Board of Trade, assured the hon. member and the House that the existing distress signals are quite distinctive, and that if they are properly used no confusion should arise. They were international signals and had worked well for many years, and the Board of Trade saw no occasion for further action or inquiry with regard to them. If the signals were improperly used claims for salvage might be made under the Merchant Shipping Act against the masters and owners of the ships so using them.

The Factories and Workshops Bill.

Nearly the whole time of the House at this sitting was occupied with a second reading debate on this measure. Without exception, the speakers expressed approval of the general scope of the Bill, although many of them advocated important changes in its several provisions. When the debate was over and the Bill read a second time it was decided, on the motion of Mr. Asquith, to refer the Bill to the Grand Committee on Trade in order that it may be thoroughly discussed in detail.

Mr. Stuart Wortley, the Under Secretary of State for the Home Department in the late Administration, made some reference to the provision requiring medical practitioners to notify certain classes of disease. This provision, he said, would have great statistical value, and might not be without preventive usefulness, but he was curious to know how the medical profession regarded it. If the Home Secretary was able to assure them that the medical profession had been made aware of the provision and did not offer any serious objection to it, then he would be satisfied and say no more upon the subject.

Mr. Tennant, who is Mr. Asquith's private secretary, and, therefore, spoke with a certain measure of authority, assured the hon. gentleman that there could be no difficulty in this connexion, because the provision simply embodied the principle of the Infectious Diseases (Notification) Act of 1889, which had worked admirably and produced most excellent results.

Mr. Henry Broadhurst called attention among other things to the cutlery trade in Sheffield. In the four years from 1888 more than half the cutlers and grinders who died in that city died from chest and throat diseases, and this mortality was caused mainly by the inhalation of particles of grit and stone. The medical officer of Sheffield had described in a recent report the shockingly unhealthy conditions in which large numbers of men carried on their work, and seeing that Sheffield was, on the whole, a rich and enterprising place and possessed a great municipality, he suggested as a means of getting at the root of this evil that municipal workshops should be erected and the poor workers released in this way from their present unhealthy dens.

Mr. Asquith made a long speech explaining further the position of the Government. In one of the clauses there would be found, he said, a prohibition as to the use of lead in the process of tinning or enamelling metal hollow-ware cooking utensils. That was founded upon evidence given before, and recommendations made by, committees that had inquired into these industries. He was satisfied that the best manufacturers did not employ lead, and that its use for that purpose was found to be most injurious. The Government had provided by Clause 30 that in certain industries, such as the making of wearing apparel, the temperature should be kept up to not less than 60° F. Complaints had been made to the Home Office by the lady inspectors, who went through the shops in London and other large towns, that during winter a number of persons employed in dress-making had to carry on their occupations in rooms which were either not warmed at all or were very insufficiently warmed, and under conditions, therefore, of great discomfort and risk of injury to health. As to the bake-houses, he proposed when the Bill got into Committee to add to the clause which deals with them a provision prohibiting for the future the use of underground premises. He was satisfied from what master and man alike had told him that both were agreed that for the future the trade ought not to be carried on in underground cellars. With regard to overtime, he did not in the least disguise the fact that he should have been glad if possible to put a stop to it altogether, but he trusted the concession made in the Bill, which was a compromise between the extreme views on the one side and the other, would be received with general acceptance.

TUESDAY, APRIL 23RD.

The Indian Government and the Purchase of Opium.

Sir Edward Grey, replying to a question by Mr. Selwyn, said that Sir James Westland was correctly reported to have stated in his Budget speech at Calcutta that the Indian Government had made arrangements for the purchase of crude opium in Malwa. The Secretary of State had no information as to the amount it was intended to purchase. Such arrangements were within the discretion of the Government of India, and did not require the sanction of the Secretary of State. Similar purchases of Malwa opium for the supply of the Indian demand had been made in previous years when the supply of Bengal opium had been short.

WEDNESDAY, APRIL 24TH.

Sale of Intoxicating Liquors (Ireland) Bill.

The House gave a second reading to this Bill, which proposes to extend Sunday Closing to the five cities now exempted—namely, Dublin, Belfast, Cork, Limerick, and Waterford; to close public-houses all over Ireland at nine o'clock on Saturday evenings; and to increase the limit qualification for bond-fide travellers from three to six miles.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

UNDER no circumstances do the Proprietors authorise the insertion of loose advertisement circulars and handbills in THE LANCET. Any such announcements are inserted by the newsagents, whom the Proprietors cannot control. At the same time, the Manager will be glad if readers will send him copies of any circulars, with the name and address of the agent through whom they obtain THE LANCET, and the Manager will then endeavour to mitigate the nuisance.

A POLITE REJOINER.

WE have received the following anonymous communication, accompanied by a newspaper cutting pasted on a postcard, for which we had the privilege of paying one penny as being "contrary to the regulations." If this is the only answer homoeopaths can give to our arguments, further remarks on the subject would seem not to be called for:—

"Put this in your pipe and smoke it. Perhaps it will tend to cool your ardour after last week's Editorial Leader.

"The Duchess of Teck will on Tuesday, July 9, open the new building of the London Homoeopathic Hospital in Great Ormond-street, Bloomsbury."

"April 18, 1896."

J. B. R.—Probably the number of cases attended in the workhouse would suffice; but she must put the question to the body whose certificate is to be sought.

H. W. Bayly.—There are no such institutions. Application must be made to the matrons of the hospitals at which the applicant desires to be trained.

COMMERCIAL MEDICINE.

To the Editors of THE LANCET.

"SIRS,—I enclose a circular, which together with an appended statement of business sent to me by an enterprising firm of surgical instrument makers, reached me the other day. With the circular there was a post-office order for 15 francs, this constituting a commission of 25 per cent. on the orders taken from my patients since 1892. I am informed that such a reprehensible transaction is quite common here in Paris, but it is as well that our confrères in England should know that we English physicians practising in this city do not lend ourselves to such undignified proceedings. I need hardly say that the post-office order has been returned with an intimation that the code of professional morality prevailing in my own country forbids any such levelling relations between physician and fournisseurs des hôpitaux.

I am, Sirs, yours faithfully,

Paris, April 23rd, 1896.

J. H. BARNARD, M.D.

"AN APPEAL."

Dr. J. B. Maurice, Lloran House, Marlborough, asks us to acknowledge the following sums on behalf of the lady whose case we published last week:—Dr. Champneys, £2; Dr. Domett Stone, £1 1s.; K. (Taunton), 10s. 6d. Further subscriptions will be thankfully received by Dr. J. B. Maurice, at the above address.

INJUDICIOUS FRIENDS AND NEWSPAPER PUFFS.—ISLE OF MAN.

We have received a paragraph from the *Isle of Man Times* on the intended departure—not just yet—of a practitioner, we regret to say, from ill-health. Much is pardonable in words of praise of a parting medical man whose health is impaired. But it is very different when the newspaper is made the medium of describing the merits of his successor. We will not suppose that either the retiring gentleman or his successor is responsible for the puff that appears in our contemporary. They will readily see that if every practitioner in the island were to be so befriended by newspapers the profession would be placed in a very undignified light, and we feel confident that we shall have their concurrence in condemning this style of paragraph.

Junior.—The information as to the case is not very complete, but a course of the ammonio-citrate of iron with iodide of potassium for some time will probably improve things. Has our correspondent tried antipyrin for the dysmenorrhœa?

C. G. H.—Yes, if it be worth the trouble; but we are not prepared to say on whom the claim should be made.

A. B. C.—All such details should be matters of contract.

ON THE TREATMENT OF IMBECILES, DEDUCED FROM PERSONAL OBSERVATIONS IN NATURAL HISTORY.

To the Editors of THE LANCET.

SIRS,—I do not know whether any of your readers have ever noticed the enlargement of the skull consequent to the growth of the cerebrum in the human species in middle or late life as the result of travelling to distant places; but I can personally testify such growth most unmistakably evident even to the extent of nearly an inch, under circumstances like those above described, at the ages of thirty, forty-five, and sixty. Another instance may be noticed in the superior proportion of the cerebrum to the cerebellum, equal to the human proportion, in birds whose power of locomotion exceeds that of the human race. This is further supported by the fact that apterous birds, as the emu, ostrich, and apteryx, do not possess this proportion and are singularly deficient in animal instinct. I do not mention this as a merely curious incident in natural history, but that, if it can be proved correct, it might lead to some improvement in the management of patients suffering from deficient cerebral development. Firstly, all the idiot asylums should be so far affiliated that patients might be removed in regular succession, say once a year, from one house to another. Change of scene would do more to develop the intellect than any kind of in-door attempt at instruction; and on arrival at a new station they should be shown about the streets and suburbs of their new location. I think this matter is well worth looking into and investigating thoroughly by the faculty concerned in such cases and by the authorities under whom they act.

I am, Sirs, yours faithfully,

WALTER SCARGILL.

Colchester, April 6th, 1895.

THE CASE OF MR. C. B. TOWNSHEND.

The following additional subscriptions have been received and are hereby gratefully acknowledged:—

Mr. W. H. Brown (Leeds), per Mr. Henry Morris...	£2 2 0	Dr. C. Y. Biss (Harley-street)	£0 10 6

HEALTH OFFICERS AND NOTIFICATION FEES.

Constant Reader.—A medical officer of health is entitled to the same fees under the Infectious Disease (Notification) Act in any and every sanitary district as any other medical man, with the single exception that he can, in respect of notification certificates arising out of his "public" practice, lay claim only to the sum of 1s. in place of the 2s. 6d. to which he is entitled for certificates of notifiable disease in regard of "private" patients.

REMOVAL OF NAMES FROM THE REGISTER.

Mr. T. Garrett Horder.—The point is of great importance. Our correspondent should supply all the facts in detail to the General Medical Council before its approaching meeting, with a request for its further action in the matter. It is obvious that local registrars should be informed of removals from the Register for infamous conduct.

FREE HOMES FOR EPILEPTICS.

R. W. (Newcastle-on-Tyne).—The provision for the unfortunate patients mentioned by our correspondent is at present most inadequate. Recent cases which are likely to receive benefit from in-patient treatment are admitted for a limited period into both the free and the contributing wards at the National Hospital for the Paralyzed and Epileptic, Queen-square (Secretary, Mr. Burford Rawlings), and the Hospital for Epilepsy and Paralysis, Portland-terrace, Regent's-park (Secretary, Mr. Howgrave Graham). For chronic cases there was until recently no provision whatever; but during the last few years three institutions have been established in this country for the admission of epileptics—viz., one for men and women at Maghull, near Liverpool; one at Chalfont in Buckinghamshire, founded by the National Society for the Employment of Epileptics (Secretary, Mr. G. P. Gaskell, 12, Buckingham-street, Strand); and the "Home of Rest for Epileptics" founded by the Countess of Meath at Godalming in Surrey, to which women and girls only are admitted. Not one of these useful enterprises, however, is at present receiving sufficient financial support from the public to enable it to admit patients without payment, although efforts are being made, we understand, at the Chalfont colony to start a special fund for this purpose. But at present payment has to be made by the patient and his friends, or by local boards of guardians, several of which are already supporting inmates both at Chalfont and Godalming. Admission to any of these homes, however, is conditional on there being no marked mental deterioration or alteration. For those epileptics who are imbecile, demented, or liable to dangerous impulses there are no public institutions available except the workhouse and the asylum. Abroad, both on the Continent and in America, the State recognises its responsibility for making provision for epileptics, and before long there is reason to hope that a similar arrangement will be made in this country.

A. B.—The fact of the tea becoming cloudy when cold is no indication of any harmful quality in the water. If our correspondent is in any doubt about the fitness for drinking of the treated water she had better send a sample to the county analyst for examination and report.

Asterion.—Our correspondent would be justified in pointing out the excess of title. It would be going a little too far to demand an apology.

TRAINING OF NURSES IN AMERICA.

To the Editors of THE LANCET.

SIRS,—A lady who is about to enter a hospital in New York for training as a nurse is anxious to know whether her holding an American certificate is likely to militate against her success on her return to England to practise. As I am not aware what repute a nurse trained in America would hold here, I should be glad if you would express an opinion.

I am, Sirs, yours faithfully,

April 25th, 1895.

"HOC AGE."

NATIONAL HEALTH SOCIETY.

The annual distribution of medals and certificates will take place (by kind permission of the Duke of Westminster) at Grosvenor House on May 11th. Her Royal Highness Princess Christian has consented to be present on this occasion, and several eminent speakers will address the meeting. Members of the society are invited to attend.

Inquirer.—The use of preservatives in milk is open to objection; but the least objectionable antiseptic, perhaps, for this purpose is borax. The only satisfactory and scientific way of preserving milk is to sterilise it by means of steam, sealing the vessel containing it before air can enter.

"WANTED, A BED-REST."

To the Editors of THE LANCET.

SIRS,—In answer to "Subscriber," I can with confidence recommend the "Core Bed-rest," made by Messrs. Arnold and Sons, as one of the most useful, practical, and economical. I have had them supplied to several of my patients, who one and all speak of their comfort and easy adjustment.

I am, Sirs, yours truly,

Weston-super-Mare, April 24th, 1895.

GEORGE B. FRASER.

MEDICAL PRACTICE AT ASHTON-UNDER-LYNE.

The following is in print:—

"Dr. — has opened the Independent Dispensary for the Benefit of the Working Classes at 88, Katherine-street, Penny Meadow, Ashton, where he may be Consulted Daily from 9 a.m. till 12 noon, and from 6 p.m. till 9 p.m. Fees:—Advice and Medicine only, 6d.; Visits within a Mile of the Dispensary, 1s."

We have omitted the name of the practitioner.

Mr. H. D. Kendall.—We would gladly assist our correspondent if we could; but it is impossible for us to reply to individual cases.

J. K. W.—We would suggest that application should be made to the Registrars of each of the Colleges concerned.

Communications, Letters &c. have been received from—

- A.—Mr. W. F. Adams, Amritsar, India; Mr. B. V. Allen, Lond.; Mr. F. W. Alexander, Lond.; Messrs. Arnold and Sons, Lond.; Abernethian Soc., Lond.; Hon. Sec. of: Army Medical Department, Lond.; Director General of: A. M. K., Lond.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 2, Rue Traversière, Amiens, Paris.

In Inaugural Address

ON

SANITARY PROGRESS AND REFORM.

Delivered at a Congress held in Manchester on April 24th, 1895.

By HENRY SIMPSON, M.D. LOND.,

CHAIRMAN OF THE MANCHESTER AND SALFORD SANITARY ASSOCIATION;
CONSULTING PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

LADIES AND GENTLEMEN,—No one can sympathise with you more keenly than I do in the disappointment you must feel at the loss of the pleasure and profit you would have derived from the address we hoped to hear from Sir R. Rawlinson, and we all share in the regret that his health would not allow of his being present with us to-day. I therefore trust to your forbearance and generosity while I venture to occupy a portion of your time this morning with a few discursive remarks. My first and most pleasant duty is to welcome you most cordially on behalf of the Sanitary Association of Manchester and Salford to this Congress, and as some of those present may know but little of this local voluntary association, you will perhaps allow me to say that it was founded in 1852 by a few gentlemen, some of whom were members of my own profession, others were clergymen, and others philanthropic laymen. Its objects were simple: (1) to promote attention to personal and domestic cleanliness, temperance, and the laws of health; and (2) to aid the constituted authorities in the promotion of sanitary improvement. The association has endeavoured to carry out these objects by: (1) the visitation of districts requiring special sanitary inquiry (one notable instance of this was the exhaustive investigation in 1888 by Dr. Thresh, now the medical officer of health for Chelmsford, into the causes of the excessive mortality of a district in Ancoats; this investigation gave a distinct stimulus to the efforts of the corporation, and was shortly followed by the condemnation of certain parts of the district by the medical officer of health as unhealthy areas); (2) familiar and well-illustrated lectures have been given in schoolrooms or elsewhere to working people; (3) there has been also the distribution of short tracts, lectures, or leaflets to the poor by ministers of religion, school teachers, and the various agents of societies employed in district visiting; and (4) the investigation and discussion of sanitary questions, and the publication of papers have also been carried on. At that time there was much cause for searchings of heart in the condition and surroundings of large masses of the population of Manchester. For a few years after the formation of the association the death-rate varied from 37.2 to 35.7 per 1000; then from 1856 to 1860 it fell to 31.6 per 1000, and the hopes of the sanitarians were raised; but in the five following years it rose again, and in 1865 was 39.0 per 1000. Though the record for Manchester was a bad one, it did not stand alone. Liverpool—of which city Manchester is supposed to be a rival in other respects than the rate of mortality—had a still higher death-rate, and for many years they possessed the discreditable distinction of being the two most unhealthy towns in the Kingdom, sometimes one and sometimes the other holding the first place. If the value of these figures is questioned from qualifying circumstances not having been taken into account, the mortality under fifteen years of age “avoids the errors arising from changes in the quality of the adult populations,” and we find that in 1861—not a particularly bad year—the rate for Manchester was 47.5 and for Liverpool 53.4 per 1000. As regards the causes of this great mortality, the geographical situation and the geological formation on which the city rests may be put aside as not affecting it specially. But the earlier records of the association show infractions of the common laws of health, which are invariably followed by disastrous results, for there is no forgiveness for those who break the laws of nature. In a report by Dr. Ransome and Mr. Royston, read at the Social Science Congress in 1866, the following are named among the causes that tend to raise the death-rate: “The narrow courts, the back-to-back houses all overcrowded with inmates, the faulty drainage, the open and fetid cesspools teeming with filth, the atmosphere charged with impurities and noxious gases, and the neglect of all

precautions against the spread of infectious disease.” Then follows a description of some parts of the town in 1854, showing that very little change had taken place during the interval. The streets were narrow and winding, and but little intersected, so that movement of air was impeded. Here and there great blocks of buildings were crowded together. Numerous courts passed out of these streets, entered by narrow arched passages, and closed often at the ends by high buildings. Sometimes these courts were a few yards wide, sometimes only a few feet, but they were lined with houses on both sides up to six or eight, or more, in number; and the sanitary arrangements were in thorough keeping with the wretched surroundings. Whole streets of back-to-back houses were common, cellar dwellings abounded, and in almost every street and court the cesspools and middens were overflowing. In some houses seven, eleven, twelve, thirteen, and even sixteen persons were living in a space with only sufficient air for the proper supply of one. Night visits were paid, and the state of things disclosed was not one we should connect with a high state of civilisation. The rooms were most offensive, the ceilings often so low as scarcely to allow of a man standing up; and lying huddled together in the same bed were men, women, and children, without regard to age or sex, and for the most part naked. Some lay on bedsteads, but the majority on the floor. Often enough four or five were in a bed lengthwise with one or two across the foot. “In every instance the windows were found closed and the inlets for air stopped up.” This life of moral and physical degradation is not one we can think of without horror and loathing; it is not one to make us glow with pride and self-gratulation on the decency, comfort, and brightness of our happy English homes. At that time the corporation had no medical adviser, and the health committee, notwithstanding its anxiety for the well-being of the city, often needed a guiding hand. This association, therefore, urged upon the authorities again and again the necessity for the appointment of a medical officer of health. As the writers of the report referred to said: “By the present method of administration authority is so much weakened and responsibility so much diluted by division that no real change for the better can be made without a complete remodelling of the sanitary department of the corporation and the appointment of a responsible medical officer of health.” And in the same year (1866) the late Mr. Turner, the eminent surgeon, at that time chairman of the Sanitary Association, addressed a communication to the authorities, urging on them the importance of making such an appointment. In one paragraph he says: “The reduction to practice of sanitary science is not, as is sometimes supposed, a mere affair of removing what are called nuisances; it involves a great deal more than this—the carrying out of building regulations, so as to secure due ventilation, supplies of water, house drainage, the management of incidental outbreaks of contagious diseases, so that their unnecessary diffusion be prevented, and the skilful carrying out of right methods of disinfection in periods of apprehended pestilence.”

As the result in great part of the representations of the association, the late Mr. John Leigh was, in 1868, appointed medical officer of health for Manchester. He was an accomplished, scholarly, and able man, and for many years did good service to the city by his earnest advocacy of sanitary improvement. He was followed in 1889 by Dr. Tatham, through whose exertions much was done to ascertain the extent of the sanitary evils under which we suffered, and to set in motion important remedial measures. We owe to him, moreover, a most valuable series of Life Tables for Manchester, first published in 1892, and afterwards extended so as to include certain recently added out-townships, which will, in his own words, “allow of the formation of a definite opinion as to how the healthiness of the people, measured by their mortality, compares with what it should be according to Life Table standards.” But, as most of you are aware, Dr. Tatham was soon lost to Manchester, and is now at the head of the Statistical Department of the Registrar-General's Office. Great was the lamentation of those interested in sanitary progress when they were deprived of his valuable services, though they were proud and glad that he should receive this recognition of his great merits, and much anxiety was felt with regard to his successor. But Manchester is sometimes, perhaps, more fortunate than her deserts, and is especially happy in the fact that Dr. Niven has already proved himself, as was anticipated by those who knew his great ability and distinguished career, worthy to follow

Dr. Tatham. And I must not pass over without mention the name of the chairman of the sanitary committee of the corporation, Alderman Walton Smith. We hear of men of one idea, but though he is a man of many ideas, he is at the same time, if I may say so, a man with one aim, with one object in life—namely, to leave Manchester a healthier city than he found it. Hospital accommodation for infectious diseases, and the removal or satisfactory improvement of unhealthy dwellings, have occupied much of his attention; and happy is it for the dwellers in our crowded towns, straggling as too many of them have to do for bare existence, when men are to be found who will devote their lives without fee or reward to helping those who cannot help themselves; and I may say here that by his warm co-operation with the medical officer of health, courts and blind alleys have been opened out, light and air have entered the dark places of the city, and thousands of unhealthy dwellings have been removed or put into a satisfactory condition—and the work is going on still. As the result of the various agencies at work for a number of years, the death-rate has gradually declined from 39 to 24 or 25 per 1000. With fewer deaths there has been less grievous sickness; the general standard of health has been raised, and the working hours of the labouring classes have been less broken in upon by illness. As Dr. Ransome says in a letter to the Lord Mayor on behalf of the association advocating the maintenance of a high status for the medical officer of health: "The result (of this fall in the death-rate) has been an enormous monetary saving to the community, represented directly by increased working time, and a corresponding reduction of expenses for medical attendance and funerals, amounting annually to many hundreds of thousands of pounds," so that the only sufferers have been the medical profession and the undertakers. But set against this the diminution of pain, sickness, and sorrow, the increased brightness and pleasure of life, and you will almost cease to pity the undertakers and the medical men. Much, however, remains to be done. The death-rate of the entire area gives little or no indication of the salubrity or otherwise of its various parts. In Dr. Tatham's recently issued report on the health of Manchester for the years 1891 to 1893, inclusive, the variation in the incidence of mortality is strikingly shown, for while Moston, one of the out-lying districts, has a corrected death-rate for the three years of 16.84 per 1000, that for Ancoats is 36.92. But even this gives too fair a picture, for, as he says, "there are considerable areas in the City of Manchester where the conditions of life are so unsatisfactory that the people die there at the average rate of 52, 56, and even 58 per 1000." But the deplorable waste of human life still going on amongst us tells most heavily on the young, and infantile mortality—i.e., "the proportion of deaths under one year of age to 1000 births"—is very great. The average for the three years varied much in the different districts, ranging from 164 in the northern division to 222 in the old township of Manchester. This mortality, however, is nearly doubled among those poor waifs born out of wedlock, of whom 411 per 1000 in the whole city perished, and in South Manchester the rate was 437. It seems almost a mockery to talk of progress in the face of such figures as these; and they abundantly prove that there must be no standing still—that the warfare against ignorance, crime, and disease must be waged with unflinching, persistent energy.

When we ask how this fight is to be fought it is well to consider the conditions necessary for healthy life. At first sight these seem simple enough, and apparently easy of attainment. We want pure air, pure water, shelter, food and clothing, and we must be temperate in all things. The first comes to us as a free gift, bestowed with lavish hand, but from birth to death we spend our time in vitiating it. In exchange for every breath we draw, gaseous and animal matters more or less deadly are given back, and if the air were still and gases not diffusible we should soon die by involuntary self-murder. Hence the need for efficient ventilation. But few applications of physical science to practice are so unsatisfactory as the various methods of ventilation. Many of them seem to consist chiefly of contrivances intended to thwart Nature's laws, rather than to obtain the end in view by soliciting her aid. Much remains to be done for sanitation in the future by the application of more perfect science, combined with a little additional common sense, to the needs of everyday life. For example, the air-supply must not be obtained from the drains and sewers, as is too often the case. It has been known to occur even in a municipal palace like this. Most of those present

will remember the painful tension in which the feelings and sympathies of the nation were held while the life of the Prince of Wales seemed flickering to extinction from illness thus produced. Nor when the source is pure must the current of air be too rapid, though often enough the current itself is blamed, when the mischief is done by that which it carries with it. No colds were caught last winter on the summit of Ben Nevis. Nor are they taken by those sleeping under the open sky in the prairies of the great North-west, even though the thermometer may be far below zero; but when the comfortable dwelling charged with impure air is reached the chances of escape are few. But in addition to the impurities of the air caused by animal life, there are the thousand-and-one modes of polluting it with trade products. Offensive trades should be carried on with all needful precautions; and if the chemical manufacturers, whose knowledge and ability we all admire, would only exercise a small portion of their fertility of resource in lessening the nuisances they create—nuisances almost more wonderful than the legitimate results of their efforts—they would bring about a happy change in many poor poisoned districts. But a glance at the programme shows that this and kindred topics will be dealt with by gentlemen far more able to do so than I can pretend to be. Of equal importance is an abundance of pure water. Until 1851 a very inferior and inadequate supply was obtained from pumps, wells, rain-water cisterns, some small works on the Medlock and at Gorton, supplemented by water from the Manchester and Stockport Canal and a well in the new red-sandstone. But in that year an abundant supply was obtained from the Longdendale Valley. Still the city grew and grew and its wants increased, so that in 1868 Mr. Bateman, the engineer, stated that the supply would only last a few years. Various schemes for obtaining more were suggested, and in the end the great Thirlmere undertaking was determined on. Terrible was the outcry against the Vandalism and vulgarity of disturbing the beautiful lake—loudest, perhaps, among those who had never been there; but the works went on for eight or nine years, and before they were completed Manchester was more than once or twice dangerously near a water famine. On Oct. 13th last the Thirlmere water was publicly turned on in the adjoining square. And if any of you will visit the lake you will find it still a thing of beauty—changed, no doubt; it is larger and fuller, looking, some may think, more noble than before, although ministering to the needs of hundreds of thousands of our fellow men. In the prosecution of this great enterprise no one rendered such invaluable aid as Sir John Harwood, who has been chairman of the waterworks committee since 1886. We have now an abundant supply for food, cleansing, and manufacturing purposes, as well as for watering the streets and cleansing the courts and alleys.

The housing of the working classes is so vast a question that I must barely touch on it. Two "unhealthy areas" have been cleared of the wretched hovels that crowded the surface and the property purchased by the corporation. It was hoped that private enterprise would have supplied the new dwellings required, but in the end the corporation had to build two large blocks of workmen's dwellings. They have been planned with great care so as to secure for each tenement good light, air, and ventilation. Each is several storeys high, and the one in Oldham-road is in the form of a hollow square enclosing an open space of an acre in extent. This plan of building seems almost unavoidable in towns from the high price of land. But I am not enamoured of these huge barrack-like buildings, where people live one above another, tier above tier, to the height of five or six storeys. Think of the toilsome journeys up and down the lofty stairs, where almost everything has to be carried; of the mothers with their babies in their arms; of what an expedition it must be for the little child down to the earth and the open air when walking is a recently-acquired art. Though separation and privacy may be obtained there must be an absence of many humanising influences. It is true that window gardening may be attempted on a small scale, but there is no little plot of ground to be cultivated in spare hours, and no return in vegetables, fruit, and flowers which does so much to ameliorate the lot of the labourer in many country districts. As a question of municipal politics, the advisability of providing dwellings and letting them at a rent which will not pay is one open to discussion. The ratepayers as a whole are taxed for the comfort and benefit of a few able-bodied citizens who have no apparent claim to such relief. As a question of public health

however, there is no doubt that they are a great improvement on the filthy, insanitary property they have superseded. May we indulge the hope that at some time in the future moving from place to place will be so easy and so cheap that the working classes will be able and wishful to live in country suburbs.

For food and clothing we are dependent on the world beyond "the silver streak." So long as our supplies come regularly we may eat, drink, and be merry. Many no doubt regret the time when we were independent of others for our daily bread, but that time has gone by, and we only hope that our supplies may never be stopped. To keep us absolutely safe with regard to this essential of our existence is, of course, the duty of every Government in power. Sanitation is not a matter affecting us only in the mass; it concerns the family and the individual, but among the majority of adults true ideas and earnestness in regard to health and life seem to permeate slowly. Great attention is now paid to the education of all, and it is to the children who will soon take our places that we must look for carrying on the work. Some there are who are a little doubtful whether, as commonly conducted, the term "education" is quite the correct one to use, and would prefer to speak of "schooling." Be this as it may, the teaching should prepare them for the citizenship which is their lot, and no better lessons can be given than such as will enable them to understand, and will help them to practise, the simple laws of health individually, and lead them on to see and to feel the duty as to matters of health that they owe to the community at large. When may we look for clear skies and pure air? When will polluted streams cease to be open sewers? If all worked together for good we might perhaps dream of a time when each one would do his duty to himself and his neighbour; when the jerry builder would cease from troubling; when the bricksetter, the joiner, and the plumber would do good, honest, well-planned work; when cleanliness and sobriety would be universal; when disease would be lessened and kept more under control. And in a good old age, in the fullness of time, life would silently ebb away like the gently receding tide. But the "ideal future" must be left for Sir Benjamin Ward Richardson to portray in the picturesque language of which he is so great a master, and we must strive, each one of us, as talents and opportunities serve, to improve the present.

A Post-Graduate Lecture

ON

SOME CASES ILLUSTRATING THE SURGERY OF THE CHEST.

Delivered during the West London Hospital Post-Graduate Course on Jan. 6th, 1895.

By STEPHEN PAGET, M.A. OXON., F.R.C.S. ENG.,
SURGEON TO THE WEST LONDON HOSPITAL AND THE METROPOLITAN HOSPITAL.

GENTLEMEN,—With regard to the troubles that may follow simple fracture of the ribs, Dr. West¹ has pointed out that fracture of the ribs is followed much more often by emphysema than by pneumothorax. This he explains by the principle of cohesion. The visceral and the parietal layers of the pleura are two moist smooth membranes, coherent everywhere; if the lung be wounded by a fractured rib driven inward, the close cohesion between the visceral and the parietal layers of the pleura prevents the diffusion of air into the pleural cavity, and thus it is driven into the subcutaneous tissue. Still, there are plenty of recorded cases of pneumothorax after fractured ribs. In one of my cases air, blood, and pus were all present in the pleural cavity. The patient, aged twenty-four, was run over, and was admitted to the West London Hospital at once, with fracture of the tenth and eleventh ribs on the right side far back; she was spitting blood, and loud rales were heard over the right side of the chest. With careful nursing she did well for a week; the spitting of blood ceased, and she was allowed to sit up in bed; but on the eighth day she was weak and ill, and had more pain in her side; the temperature

was 102° F. and the respirations 50. There were signs of pneumothorax in the front of the chest; behind there were signs of a collection of fluid. On the thirteenth day an aspirator was put in at the fifth space, near the angle of the scapula, and eight ounces of dark fluid blood were drawn off. This gave her great relief; but on the nineteenth day it was necessary again to use the aspirator, and this time the blood that was drawn off was mixed with offensive pus. A week later I made a free incision, letting out six or seven ounces of thin, brown, turbid, offensive fluid, mixed with gas, and put in a large tube. No more fluid came out during the operation, but a few hours later there was a profuse rush of it, soaking the bed. She did well after this; the tube was left out on the seventh day. I delayed making the incision in this case because, in spite of the presence of offensive pus in the chest, she was daily gaining ground in her general health, and I was anxious not to run the risk of causing fresh hæmoptysis by giving her an anæsthetic, or of reducing her strength by any operation till it was absolutely necessary.

Acute pneumonia or broncho-pneumonia after fracture of the ribs may be due to other causes besides injury of the lung: such as the shock of the accident, the exposure after it, the sudden enforced rest in bed, the impairment of the movements of respiration, and the difficulty of clearing the bronchi by coughing. A woman aged fifty was run over and admitted under my care with fracture of the third, fourth, and fifth ribs, and laceration of the vagina. Bronchitis was marked on the third day. Two days later there was pneumonia on the same side as the fractures; she lay on the injured side, and hardly moved it in respiration; the whole lung was rapidly involved, her breathing became laboured, and she sank and died on the tenth day. Another case was that of a man aged thirty-nine, who fell out of a cart. He had severe concussion, fracture of several ribs on the right side, other slight injuries, and chronic bronchitis. On the third day he had acute pneumonia, the temperature being 103° F., the breathing laboured, and the face dusky. That night he was bled to ten ounces with immediate relief; he began at once to improve and made a good recovery. Leeches had failed to do him any good, and I feel sure he owed his life to the bleeding. In a case of hæmothorax after fractured ribs bleeding gave relief, though it did not save the patient's life. A man aged forty-five was crushed in a carriage accident; his ribs were fractured, and he sustained a bad compound fracture of the leg. On the third day his pulse and respiration rose to such a height that he was bled to nine ounces. He was greatly relieved and got some sleep, but the relief was only temporary and on the fifth day he died. We found no less than thirteen ribs fractured, seven on one side, six on the other; the right lung was lacerated and there was blood in the right pleural cavity. Probably in such cases as these nothing gives so much relief or is so likely to save life as a moderate bleeding.

Passing from injuries of the ribs to diseases of the ribs, it is worth our while to note how seldom the ribs are the seat of tumours, either innocent or malignant. It is true that in the last stages of melanotic cancer the ribs may become infiltrated with the disease; but with this exception the ribs are rarely attacked by malignant disease, either primary or secondary—not even in cases of advanced cancer of the breast. It is the medulla of the bones that receives the secondary deposits of malignant disease, and perhaps the ribs owe their immunity to their having so little medullary tissue. But, beside this, the distribution of secondary growths in malignant disease is not a mere matter of chance; some parts of the body are much more apt than other parts to receive and nourish the cancer cells that are carried to them by the blood. I once tabulated the distribution of the secondary growths in many hundreds of cases of cancer of the breast, and it is certain that some bones, especially the upper third of the shaft of the femur, are more favourable for secondary deposits than other bones are; the cancer cells may be carried all over the body, but they do not find a congenial soil everywhere.

The diseases of the ribs, then, are mostly diseases of inflammation—periostitis, caries, and necrosis; and most of the patients are tuberculous or syphilitic. As an instance of tuberculous caries a little boy came under my care with a chronic abscess over the lower ribs on the left side in the mid-axillary line. It was incised and

¹ Bradshawe Lecture on Pneumothorax, 1887.

drained, and it healed well; but two months later he came back with caries of the lumbar spine, and where the abscess over the ribs had been there was now a deep depression of the wall of the chest one and a half or two inches in diameter. There is another cause of caries of the ribs besides tubercle and syphilis; it may occur after one of the continued fevers, especially typhoid fever. A man forty years old had typhoid fever in the spring of 1891, and this was followed by periostitis of both tibiae and of one of the lower left costal cartilages. As regards the nodes on the tibiae, one became absorbed, and the other suppurated and healed without exfoliation. The swelling of the costal cartilage suppurated and was incised, but did not heal; and in December, 1892, he had a sinus there three and a half inches long. I cut down and opened it at its lowest point, and scraped a carious patch on one of the costal cartilages, but still it did not heal. In November, 1893, I laid open the whole sinus and found a small, deep, thick-walled cavity, leading to a costal cartilage which was cut right across by caries. I removed the carious ends of the cartilage and the thickened tissues round the sinus, and kept open the greater part of the cavity; but fresh sinuses formed, and these also had to be laid open, and then at last the whole wound healed. Keen³ of Philadelphia collected 69 cases of diseases of bone following one or other of the continued fevers; the large majority were cases of typhoid fever; most of them were those of men; and his list includes almost all the bones in the body. In 22 cases the bones of the head or the face were attacked, in 7 the trunk, in 6 the upper limbs, and in 42 the lower limbs. Necrosis occurred in 50 cases, caries in 12. As regards the interval between the onset of the fever and the onset of the bone disease, in 10 cases it was a fortnight; in 27 it was from three to six weeks; and in 10 cases was more than six weeks. Caries or necrosis of part of a rib, whatever its cause, is so likely to set up sinuses burrowing in all directions, even down the whole length of the abdominal wall, that we are justified in operating on these cases, but the operation must not be done in a half-hearted way; the bone must be scraped or excised, and every sinus must be carefully laid open to the very end.

As regards pleural effusions I should like to mention a case of serous effusion due to cancer of the pleura secondary to cancer of the breast, as it has some points of practical interest. I removed the right breast in March, 1890, and removed a recurrent nodule in November of the same year. In April, 1891, the patient had signs of right pleural effusion; and it is worth noting how quickly the fluid was poured out. On the first occasion I drew off forty-three ounces; ten days later fifty-three ounces; eleven days later thirty ounces; a week later fifty ounces; and eight days later forty-three ounces. Three days later her sufferings came to an end; they had been much relieved by the use of the aspirator, and it was curious to see how she fell asleep after it, just as patients do after tracheotomy. I have seen the same sudden sleep on two or three occasions in a case where I had several times to puncture the abdomen for acute distension—the so-called idiopathic dilatation of the colon.⁴ And another case of non-purulent effusion is worth mentioning here, though I only know of it by hearsay. A young man aged nineteen after some trifling ailment was found to have some enlarged glands in the left axilla. A surgeon in Paris operated on him, making a transverse cut right across the axilla from the pectoral muscle almost as far as the trapezius, and clearing out the glands; after this he used to put his finger into the wound day after day and clear out whatever he could. The young man's blood was examined, and he was declared to have leucocythæmia. Then some obstruction of the lymphatics of the arm set in, and his arm began to exude lymph, to the extent of several ounces daily. The axillary wound was full of indolent granulations; the arm was blistered with vesicles containing lymph; then came signs of pleural effusion on that side of the chest, and the fluid that was drawn off had large flakes of lymph floating in it, and coagulated rapidly to a firm clot. He wasted rapidly, probably from some obstruction of the thoracic duct, and so died.

For exploring the chest a small syringe with a long strong steel needle is better than an aspirator—easier for the

surgeon, less warning to the patient, and less likely to wound the lung; cocaine will do for an anæsthetic provided it be injected under the skin, not painted over it. Of course, one must avoid the intercostal vessels, and the needle must not be thrust through any thick muscle. In one case, an empyema of the right side containing sixty-five ounces, a surgeon had put the needle of the aspirator through the whole thickness of the pectoral muscle; this was followed by an abscess beneath the muscle communicating with the empyema.

If the empyema is already pointing outside the ribs we must of course make a free incision into the swelling, but it does not follow that we shall be able to make out the communication between the swelling outside the ribs and the empyema inside them. I have had three cases of empyema pointing outside the ribs. In one, that of a boy aged nine, an empyema of the left side had already burst through the skin, leaving a fistula, high up, between the second and third ribs, close to the sternum. When one pressed the chest, pus poured from the fistula, but one could not get a probe through it. In another case, that of a young man, an empyema of the right side had pointed over the seventh, eighth, and ninth ribs in the anterior axillary line, and had been mistaken for a simple superficial abscess. I opened it freely, but could not make my way from it into the chest. In the third case, that of a man aged forty-eight, the empyema pointed at the same place, and here, on opening the swelling, I did come straight on a large hole between the ribs into the chest. Thus, in two cases out of three, the place where the empyema pointed was no guide as to the place where one ought to evacuate it. In many cases, of course, one cannot do better than follow the track of the exploring syringe. But it happens to every surgeon now and again to make his opening too high or too far forward for proper drainage of the cavity, and if he does this he had better make his counter-opening at once, or he will certainly have to make it afterwards. As regards the resection of part of a rib, this can hardly be avoided in children; but in adult patients the ribs may be far enough apart to admit a full-sized tube. In one of my cases there were no less than 105 oz. of pus, mixed with large masses of fibrin; but it was all let out by simple incision without resection, and the cavity was healed in a few days. Still, it is a very simple matter to remove an inch of a rib, and it allows the surgeon to examine the cavity with his finger. If the pleura be much thickened it is better to open it with a scalpel than with a director.

There remain for our consideration some important points as to the course, treatment, and termination of cases of empyema.

Empyema may be due to the extension of suppuration downward from the neck or upward from the abdomen, and it may itself extend downward in various directions. Some time ago a child came under my care with a mastoid abscess. This was opened and drained; then came a deep abscess in the neck, which was also opened; then came empyema—all being on the same side. Bouchut⁵ has recorded the case of a girl in whom an empyema of the left side of the chest was due to a long sinus on the left side of the face from caries of the malar bone, and Sir W. Dalby had a case where pus burrowed downwards from the mastoid bone, along the sterno-mastoid, to the lower border of the thyroid cartilage, and also under the splenius and complexus muscles. As regards the downward wandering of empyema, a man aged forty after acute double pneumonia had empyema of the left side. This was opened and drained, and about three weeks afterwards I allowed him to get up; but that very day his temperature began to rise and fluctuate, and he began to lose ground; a few days later, he had pain down the leg, and kept it flexed; then came an acute swelling in Scarpa's triangle, and here I opened a large abscess passing up into the pelvis out of reach of my finger, and also burrowing backward in the thigh, round the inner aspect of the femur, so that a counter-opening had to be made between the hamstring muscles, and then it all healed without any more trouble. A very good collection of cases of this wandering sort of empyema has been published by Bouveret.⁶ Some went into the lumbar region, and one of these pulsed like an aneurysm; others went into the gluteal region; others made their way to the umbilicus. Bouveret points out that

this extension of empyema occurs almost always on the left side, and in young people.

As to the after-treatment of empyema, probably we are all agreed that it ought not to be washed out at the time of operation; it cannot be safe to do it while the patient is anaesthetised, so that he cannot tell the surgeon anything, or expel the lotion by coughing. After the first two or three days I usually wash out the cavity once a day; one often finds shreds of lymph and small clots of blood which are doing no good inside it. Of course the lotion must not contain any poisonous substance; and of course it must be of a proper temperature. I know a case where cold lotion was used for washing out a child's chest, and the child died at once. In 1877 Dr. Cayley⁷ published the case of a man aged thirty-six who had repeatedly had an empyema washed out; but one day the washing out was at once followed by convulsions, opisthotonos, and death in sixteen hours. Vallin had a case, that of a man aged twenty-three, where washing out an empyema was followed by convulsions and opisthotonos; death ensued in six hours. Raynaud had a similar case, but the patient recovered. Lorey had a case, that of a man aged twenty-seven; his empyema had been washed out daily for three weeks, and then one morning the washing out was followed by syncope and convulsions; these passed off, and he repeated the washing out that evening; again there was syncope, and again convulsions, and this time the patient died in a few hours. These cases remain unexplained. In all of them the washing had been done day after day, week after week, and nothing had happened. No cerebral embolism or thrombosis was found; none of the post-mortem examinations showed anything special. Dr. Cayley, in his account of the whole subject, can find no definite explanation of it.⁸ The only trouble I have had in washing out was in a young man whose empyema I had washed out daily for a week; one day later I washed rather too hard, and suddenly he had a fit of coughing, a sharp pain in his side, a foul taste in his mouth, and he coughed up a streak of blood, and for some hours he felt very weak and low: no harm came of it—I must have torn some adhesion.

From time to time cases are recorded where the drainage-tube has fallen into the cavity or has been sucked into it. This stupid accident has twice happened to patients under my care. I have collected all the recorded cases I can find, and they make one thing clear—that the tube must not be left there. In both my cases I was able to find it very easily with long, slender urethral forceps, which can pass down a very narrow sinus and then open very wide, so that the whole cavity can easily be explored. The tube generally falls to the back of the cavity and lies alongside of the spine, but if there are adhesions or bands of scar tissue round the opening into the cavity it may get caught among these close to the ribs.

I have to refer to a very unhappy case where the patient suddenly died on being turned on his side for operation. A boy ten years old was admitted with dulness over the whole left side, and marked bulging of the chest wall. Chloroform was given, and he was turned partly over on to the sound side without any bad result. After waiting a little I turned him over a little further and made my incision. At this moment he stopped breathing, but the pulse continued, and the anaesthetist did not at once notify the cessation of the breathing. Then the pulse stopped, and neither by letting out the pus nor by artificial respiration were we able to save his life. No post-mortem examination was allowed. This disaster would probably not have happened if I had first aspirated the chest without taking the boy out of bed at all, or if, as would have been quite easy, I had drawn him just over the edge of the operating table and had then knelt underneath him, and so let out the pus without turning him over.

In two cases empyema was combined with or followed by tuberculous phthisis. In March, 1894, I operated on a young man aged twenty-three for an empyema of the right side containing about two ounces and a half of sero-purulent fluid, and for the next three weeks he did very well, save only that his temperature remained high at nights. As this did not improve I made a counter-opening lower down and

further back, but still the cavity did not close. Then he went home into country air, but still he did not heal; and about three months after he went home he was found to have signs of pulmonary phthisis. In another case, which is now in the hospital, the empyema healed quickly; but there are signs of commencing phthisis of both apices, which were not present when the patient was admitted a month ago.

There is a form of empyema where the pus is intensely fetid, of a horrible gangrenous smell—thin blackish fluid so virulent as to cause sloughing of the muscles all round the wound, with delirium, sweating, diarrhoea, rigors, and great prostration. In one case, that of a man aged twenty-five, I let out more than a pint of thin, blackish, horribly gangrenous fluid. I kept the cavity clean with frequent irrigation, but there was extensive sloughing of the intercostal and trapezius muscles; he never rallied from the state in which he had been since admission, and he died on the tenth day after admission. In another case, that of a woman aged twenty-four, we let out thirty ounces of similar thin, dark, gangrenous fluid. She lay for nearly a fortnight in the same typhoidal state as the first patient, delirious at times, passing everything under her and refusing food; there were the same sweats and diarrhoea and the same sloughing of the muscles round the wound. At last she began to improve, and recovered. There was no evidence in either case during their illness, or in the first case at the post-mortem examination, of gangrene of the lung—no fetid sputa, no shreds of lung tissue in the discharge, and no free air in the pleura.

As regards gangrene of the lung I had an instrument made some years ago with the idea that it might be useful for the evacuation and drainage of deep cavities in the lung, the liver, or the brain. In such cases the pleasure of finding pus is often marred by the difficulty of getting a tube into the cavity without lacerating the surrounding tissues; nor is it easy to be sure that the tube is just the right length. The instrument is a director 7 in. long, cylindrical, the same size all the way, deeply hollowed out, marked in half inches all the way, and cut off short without any handle, so that a tube can be slipped down over it. Four silvered tubes fit smoothly over it, and they are exactly 1½, 2, 2½, and 3 in. long. There is a collar to fit any of the tubes, with holes in it for threads to keep it steady. When you find pus with this director you know to half an inch how deep it lies; then you take a tube, or a bit of drainage-tube, of exactly the right length, and slip it down over the director. Thus you avoid the chance of missing your way or of damaging the tissues with that clumsy and unclean instrument, the polypus forceps.

CASES OF INTESTINAL ANASTOMOSIS BY MEANS OF THE MURPHY BUTTON.

By J. ERNEST LANE, F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS AND LECTURER ON ANATOMY, ST. MARY'S HOSPITAL; SURGEON TO THE LONDON LOCK HOSPITAL.

THE following cases, for the notes of which I am indebted to my late house surgeon, Mr. A. L. Jackson, exemplify some of the uses of the Murphy button in abdominal surgery.

CASE 1. *Carcinoma of the pylorus; gastro-enterostomy.*—A single woman aged fifty-five years was admitted into St. Mary's Hospital on Nov. 13th, 1894, with symptoms indicating obstruction at the pyloric orifice of the stomach. She had for six months previously been unable to retain any solid food in the stomach, but was constantly sick after her meals; she had on several occasions vomited blood, and had been reduced to a condition of extreme weakness and emaciation, her weight, which had been over 9 st. before the commencement of these symptoms, having fallen to 7 st. 2 lb. She had been operated on ten years previously for exomphalos, and the umbilical region was still occupied by a hernial protrusion of considerable size. Somewhat below the normal situation of the pylorus a hard, nodular, and mobile swelling could be detected, and the area of stomach resonance was greatly increased. The diagnosis of carcinoma of the pylorus was made, and it was decided to perform gastro-enterostomy, and if possible pylorotomy. On Nov. 20th the abdomen was opened in the middle line in the epigastric and umbilical regions, and the dilated stomach was at once perceived; on

⁷ Transactions of the Clinical Society, 1877, p. 16.

⁸ Some curious cases are reported by Lépine (Union Médicale, Feb. 1st, 1878) where the evacuation of an empyema or the subsequent irrigation of the cavity was followed by slight temporary loss of power in the upper or the lower limb on that side.

tracing this to the right a hard nodular growth was found implicating the pylorus and the commencement of the duodenum, but adhesions of its posterior surface to subjacent parts rendered impracticable any attempt at pylorotomy. I was, therefore, compelled to content myself with gastro-enterostomy, in the execution of which some difficulty was encountered owing to the numerous adhesions which existed between the great omentum and peritoneal folds in its vicinity. After some delay the small intestine was exposed and followed up to the commencement of the jejunum, into which the male half of a large-sized Murphy's button was introduced; the female segment having been inserted into the lower part of the great curvature of the stomach, the two portions of bowel were accurately approximated. The subsequent course of the case was uneventful; the patient was able to assimilate the ordinary hospital diet within a month from the operation, and on Dec. 25th was able to enjoy the traditional Christmas dishes. She left the hospital on Jan. 12th, her weight being then 8 st. 11 lb. At the present time (April 28th) her condition is eminently satisfactory, the growth seems to be quiescent, and her weight is 10 st. 6½ lb., being an increase of 3 st. 4½ lb. since the operation; the button, however, is still retained, it being now 160 days since its insertion; the only evidence of its presence is an occasional pricking sensation in the epigastric region.

CASE 2. Strangulated inguinal hernia; gangrene of intestine: resection and anastomosis.—A man aged fifty years was admitted to St. Mary's Hospital on Jan. 29th, 1895, suffering from a strangulated inguinal hernia of four days' duration, which four days had been spent in aggravating his condition by means of drastic purgatives and irritating local applications. When summoned to see him I decided upon immediate operation and accordingly cut down upon the large scrotal swelling which was present on the right side; the sac was found to contain a quantity of fetid fluid of brown colour, and the bowel for about two inches in length was black and gangrenous, and in a condition which allowed no hope of its recuperation. The intestine was clamped and five inches of it were resected together with a wedge-shaped piece of mesentery; the divided ends were then brought into contact by means of the medium-sized Murphy button, and the edges of the mesentery approximated by sutures. As the patient was somewhat exhausted it was not considered advisable to attempt the removal of the large hernial sac, but it was rendered as far as possible aseptic by applications of a 1 in 20 carbolic lotion, and subsequently a large drainage-tube was introduced. A few days after the operation the patient had an attack of delirium tremens and had to be kept under the influence of morphia; the operation wound also became septic and discharged a considerable quantity of very offensive pus; further than this a troublesome diarrhoea supervened, and it was only with difficulty that the patient's strength was sustained. Ultimately, however, he rose superior to all these complications and on Feb. 12th was able to take solid food; on Feb. 17th he complained of uneasiness in the rectum, and on examination the button was felt and was without difficulty removed, nineteen days having elapsed since its introduction; after this convalescence was uninterrupted. I have since learnt that this patient is in perfect health; his bowels act well and freely, and he feels as well as he did before the operation.

CASE 3. Strangulated femoral hernia; perforation of intestine: enterectomy and anastomosis.—A female aged sixty-two years was admitted to St. Mary's Hospital on the evening of Feb. 25th, 1895, suffering from a strangulated femoral hernia of seven days' duration. Throughout this period opium had been administered and taxis had been several times tried with no result, and stercoraceous vomiting occurred shortly after her admission. The patient having been prepared for operation I cut into the hernial sac, and there discovered a loop of bowel three inches in length in an acutely strangulated condition. On incising the neck of the sac and drawing down the bowel for a more minute inspection a small perforation was detected at the proximal end of the portion involved. A resection to the extent of seven inches was then effected, and the divided ends were brought together by means of the medium-sized Murphy button. Some difficulty was experienced in securing the vessels at the apex of the wedge-shaped portion of the mesentery which had been removed, and after the bowel had been returned into the abdominal cavity there was considerable oozing therefrom; the loop was, therefore, again drawn out, and a bleeding

point which had hitherto escaped notice was ligatured; the peritoneal cavity was thoroughly cleansed by the introduction of sponges on holders. The patient's rallying powers were insufficient to tide her over the shock resulting from the somewhat protracted operation, and she succumbed thirty hours afterwards. At the necropsy the divided ends of the intestine were found to be in perfect approximation, and some adhesion between the opposed serous surfaces had already taken place; there was no sign of peritonitis, and death could only be attributed to shock.

Remarks.—A perusal of Professor J. B. Murphy's paper in THE LANCET of April 27th prompts me to put on record my at present limited experience of the ingenious contrivance which bears his name and which seems destined to effect a revolution in intestinal surgery. In the list which he has compiled Professor Murphy has included very few cases recorded in this country, and it may be a source of gratification to him to find that his method has met with a far wider recognition among English surgeons than he has hitherto imagined. In proof of this statement I may point out that Mitchell Banks has recorded two cases of enterectomy, of which one was successful;¹ Hamilton² and C. A. Morton³ successful cases of enterectomy; while E. Owen, in THE LANCET of April 27th, describes a case of resection of the intestine for cancer of the colon, and Arbuthnot Lane⁴ describes a pylorotomy and gastro-enterostomy in which (I learn from him) the patient succumbed six days after the operation to the disease, advanced carcinoma of the pylorus. In a previous communication⁵ Professor Murphy has drawn attention to the remarkable reduction in the mortality following enterectomy and kindred operations when performed with his button, and this reduction is rendered even more conspicuous in the light of the cases tabulated in his later contribution. A not unnatural reluctance to publish failures exists in every occupation in life, and surgeons are not altogether exempt from it; but even if all the unrecorded cases where the Murphy button had been used without success could be collected it is doubtful whether they would exceed the unsuccessful cases resulting from other methods, which had in like manner not been deemed worthy of publication. Further, the reduced mortality in intestinal operations with Murphy's button is so remarkable that even if a considerable number of fatal cases was added to the list it would still compare favourably with other methods. Take, for instance, the mortality following resection of the bowel for gangrenous hernia—there are in Murphy's list fourteen cases and two deaths, to which may be added my cases, which will give a total of sixteen cases and three deaths, or a mortality rather under 19 per cent.; and here the element of personal skill may be entirely excluded, for the sixteen cases were in the hands of eleven different operators. The statistics of Zeidler of St. Petersburg⁶ show a mortality of 49 per cent. in 289 cases of primary resection of gangrenous hernia; even if we take into consideration the fact that these figures refer to a far larger number of cases the disproportion between 19 per cent. and 49 per cent. could hardly be accounted for by the difference in the number of cases tabulated. Retention of the button has been known to occur, though I find no mention of it in Professor Murphy's tables; he, however, in his answer to Dr. Wiggan's criticisms⁷ mentions that two such cases had been reported to him. In my case of gastro-enterostomy the button has been retained for 160 days, and the intestinal tract has up till now shown no resentment at its presence. I have not followed Professor Murphy's advice to explore the rectum in the hope of discovering it, for I imagine it has found its way into the disused portion of the duodenum, and so the occasional "pricking sensation" which the patient experiences in the epigastric region may be accounted for; whatever the situation, it is not productive of any signs of irritation, and its retention has been in no way prejudicial to the successful issue of the case. My second case is noteworthy on account of its numerous complications—viz., delirium tremens, severe diarrhoea, and sepsis. The latter was, I believe, unavoidable, for the patient was not in a condition to permit of the prolonged dissection necessary for the removal of a large hernial sac, and had I attempted this the issue of the case might have been different. I decided

to leave an extensive source of sepsis in the shape of a sac which had contained gangrenous bowel in preference to prolonging an operation on a not very promising subject, and I trusted that I might counteract this element of danger by subsequent treatment, and in my humble opinion the result of the case justified the course I pursued. The death of my third and last patient was a source of great disappointment to me, but as far as the button was concerned no blame can possibly be attached to it, for it was proved to have answered its purpose perfectly. As will happen on certain occasions, everything seemed to conspire against a favourable issue: a delay of seven days from the commencement of symptoms of strangulation may justly be instanced as an example of "criminal procrastination," and the administration of opium during that period was an aggravation of the offence, while the difficulty in controlling the hæmorrhage from the mesenteric vessels was the proverbial last straw.

Queen Anne-street, W.

A CASE OF SCLEREMA NEONATORUM ENDING IN RECOVERY.¹

By ARCHIBALD E. GARROD, M.D. OXON.,
F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, AND TO THE WEST LONDON HOSPITAL.

SCLEREMA NEONATORUM is so rare a disease, and when met with so seldom has any but a fatal ending, that I venture to publish a case which has been recently under my care and which ended in complete recovery, believing that in the present incomplete state of our knowledge of this and allied conditions the period has not yet arrived when such records are superfluous.

The patient, a male infant aged five weeks, was brought to the out-patient department of the Hospital for Sick Children at Great Ormond-street on Nov. 5th, 1894. The mother, a healthy-looking woman, stated that this was her third child. Of the other two the elder was strong and well, but the second died in consequence of a fall at the time of its birth. The last pregnancy was preceded by a miscarriage at the third month. The father was said to be healthy. The family occupies three rooms on a first floor and no history of privation was obtained. The infant was born at full term, the head presented, and there was no particular difficulty at the birth except that the hæmorrhage was somewhat excessive. He was a well-nourished and, except in one respect, a healthy child. There was not, and had not been, any rash upon the buttocks or snuffles. The child was being suckled by his mother, who had an abundant supply of milk, which he took regularly and well. The back of the infant presented a remarkable induration, which extended, like a kind of carapace, over almost the entire dorsal aspect of the body, involving the deltoid regions and upper arms, the buttocks, and the thighs down to and including the popliteal spaces. The skin of the face, front of the trunk, and limbs was perfectly soft and natural. The edges of the indurated area were sharply defined, irregular, and maplike, and there was nowhere any tendency for the hardened to merge into the healthy parts. The skin over the affected parts was stretched, but not shiny, and in places exhibited a pink mottling; it could not be pinched up between the fingers; pressure produced no pitting, but merely rendered the surface pale for a time. The distribution of the induration was remarkably symmetrical. The legs could not be fully extended either at the hips or knees, and when extension was attempted the skin in the popliteal spaces became very tense and shiny. There was no swelling, cedematous or other, of the hands or feet. The child was good-tempered, and the examination did not appear to cause it any pain or discomfort. There were no signs of any disease of the heart, lungs, or other viscera, and there was no intestinal disturbance. The urine was not examined. It was stated that the induration upon the buttocks was noticed immediately after birth, and the places were at first of a deep pink colour. During the first nine days of life the hardness spread down the thighs, but as far as could be ascertained the extension to the back and arms only took place during the fifth week, just before the

infant was brought to the hospital, by which time the colour of the affected parts had become much paler than formerly. No history of any surface exposure to cold air or water could be obtained. Inunction of a drachm of cod-liver oil night and morning was prescribed. The note of Nov. 12th, a week later, states that the induration in the dorsal and lumbar regions was rather less marked, but there was no noticeable change in other parts, except that the redness had practically disappeared. The general health continued good, the infant sleeping and taking his food well. There was no coldness of the skin or extremities, and the temperature taken in the rectum was 98.2° F. On this date inunction of blue ointment was ordered in place of the cod-liver oil. By Nov. 19th there was decided improvement in the local condition. The skin of the back, although it appeared stiffer than that of the normal parts, no longer exhibited marked induration; the hardness in the deltoid regions had disappeared, but a small patch remained upon each upper arm. The hardness of the buttocks and backs of the thighs—i.e., of the parts first affected—was as distinct as ever, but had somewhat diminished in extent, and the hide-bound condition in the popliteal spaces was less marked. It was a noteworthy fact that as the induration cleared up it did not merely shrink at its borders, but isolated patches were left which had become detached from the main area. Moreover, no pitting could be elicited in the regions in which the affection was clearing up. The note of Nov. 26th says that by that date further improvement was evident. A very small patch of induration was noticed in the left parotid region, which had probably been previously overlooked. On Nov. 29th the rectal temperature was 99°, and the induration had still further diminished in extent. On Dec. 13th there were still isolated patches upon the upper arms and extensive induration over the buttocks. On this date the inunction of mercurial ointment was stopped, and that of cod-liver oil was ordered to be resumed. On Jan. 31st, 1895, there was only a small patch of induration upon the outer surface of each thigh and the child could extend its legs well. The arms and back were entirely free. By March 14th the induration had completely disappeared; there was a slight cough, but no abnormal signs were detected in the chest. The infant was good tempered, well nourished, and slept and took the breast well. On April 18th the child weighed fifteen pounds and three-quarters. The temperature in the rectum was 99.4°.

From the typical cases of sclerema neonatorum, upon which the descriptions contained in the text-books are mainly based, the above case presents certain well-marked differences, which, after all, are differences of degree rather than of kind, and which may be briefly summed up as follows: 1. The child, instead of being weakly at birth, was, with the exception of the local condition, in excellent health; nor had he suffered at any period of his brief existence from any pulmonary or intestinal disorder. 2. The temperature as taken in the rectum was at no time exceptionally low, whereas in severe cases the depression of temperature is one of the most conspicuous phenomena of the disease. The rectal temperature of 98.2° in the earlier stages probably indicated some depression, for it is stated that in young infants the temperature is as a rule over 99°, and on later dates the temperature was always somewhat higher in this case. 3. The induration after spreading in the earliest weeks of life became arrested, and instead of succumbing to the disease the patient made a steady and complete recovery. Now the only recognised condition with which sclerema is liable to be confused is the cedema sometimes observed in newly-born infants. There is no doubt that these two phenomena have frequently been confused together, and such confusion permeated the earlier literature of the subject until Parrot clearly differentiated between them, pointing out that Andry and other French authors had applied Underwood's name of sclerema to a quite different condition from that which he intended it to designate. Those who are interested in this question will find the differences between sclerema and cedema neonatorum clearly set out in Henoch's work on the diseases of children, and in a paper by Dr. Ballantyne.² In their general condition infants which are the subjects of sclerema and of cedema are apt to resemble each other somewhat closely, but the integuments of cedematous infants usually pit on pressure, although when there is great tension of fluid this character may be to a great extent wanting. Again, whereas sclerema tends to commence upon

¹ A paper read before the Medical Society of London on April 22nd, 1895.

² Brit. Med. Jour., vol. i. 1894, p. 403.

the dorsal aspect of the body and legs, and thence to spread to the remainder of the surface, oedema is apt to appear in the hands and feet and early involves the abdominal walls and scrotum or labia. I do not think that the case which I have described was one of oedema, for the following reasons: 1. There was no evidence of syphilitic taint in the child, and the history of a miscarriage preceding the pregnancy hardly suffices as evidence of this disease; nor was there any evidence of erysipelatous inflammation, of visceral lesions, nor, indeed, of any recognised cause of oedema. 2. The distribution of the hardness and the manner in which it cleared up, leaving isolated patches which persisted for a long time, seems to me strongly opposed to the diagnosis of oedema. 3. The absence of pitting on pressure even in parts in which the induration was disappearing, and the tension could no longer be excessive, seems incompatible with such a diagnosis. I should, however, mention that when the patient was shown at the Dermatological Society in November, 1894, some of those present expressed the opinion that the condition was rather of the nature of oedema than of sclerema. If I am in error in describing the case as one of sclerema I have erred on good company, for among the published cases of that disease I have found several recorded by eminent observers which were obviously of the same nature as that under consideration.

I may perhaps be permitted to refer briefly to some of these examples. In THE LANCET for 1889³ Dr. Angel Money recorded the case of a female infant aged five weeks. At the time of birth a patch of induration was noticed on the right shoulder and another in the left parotid region. The skin was hardened all over the back of the trunk and on the buttocks and thighs, and in other parts was normal; no mention is made of the colour of the affected regions. The muscles were well developed, the spleen was palpable, but there was no other evidence of visceral disease. The rectal temperature was 99.2°. There was no evidence of syphilis. Up to this time the induration had been spreading, but afterwards steadily decreased, and six weeks later there only remained a small patch, about the size of a pea, in the left parotid region, and one of the size of a sixpenny piece in the left deltoid region. The child continued well and strong. Dr. Money was inclined to attribute the favourable result to the inunction of blue ointment. The resemblance of this case to mine is very striking, and is shown in the distribution of the affection, in the absence of pitting, in the manner of clearing up, leaving detached islets of induration, and in the absence of low body temperature or other signs of ill-health. Dr. Barlow records the case⁴ of a feeble infant first seen nine days after birth. Over the greater part of the back, on the shoulders, and on one thigh the skin had a bluish-red colour, was raised above the surrounding level, and exhibited marked brawny induration. The surface was not hot, and no pitting was elicited on pressure. No glands were enlarged, and there were no signs of heart trouble or of atelectasis. Three days later the induration of the back had extended downwards, and there was some induration on the front of the right arm. A week later the child was brighter and better, but the induration was still spreading, and had involved the nates and backs of both thighs. Seventeen days later the induration was slowly clearing up, and the affected skin was paler. In the course of the following three months the sclerema disappeared entirely with the exception of one or two minute fatty indurations on the middle of the back. The treatment adopted was inunction of the affected parts with camphorated oil, and small doses of cod-liver oil by the mouth. Here the patient was seen at a considerably younger age, and the redness, which in my case had to a great extent disappeared by the time that the child came under observation, was a conspicuous phenomenon. Another example, in which a vividly red area of induration was confined to the buttocks and backs of the thighs of an infant a month old, was recorded by Dr. A. G. Barra.⁵ Grey powder was administered, and the infant recovered. A somewhat similar case will be found recorded by Dr. A. R. Robinson.⁶ Evidently the case which I have described is one of a group of cases tending to recovery, all more or less closely resembling each other, and which, whilst they differ in certain respects from the typical examples of sclerema, exhibit still more conspicuous differences from the oedema of new-born infants as it ordinarily presents itself. Possibly

when future research shall have thrown more light upon these obscure conditions it may turn out that such cases constitute a third distinct group differing in their essential nature from either of the conditions under discussion. Of the morbid anatomy of the condition present in such examples as these nothing is of course known, but we are not without knowledge of the changes present in fatal cases of sclerema. Some writers have described a deposit of stearin-like material in the subcutaneous tissue, suggesting that the fat there present has become solidified, and accordingly the name of fat sclerema has been employed. The theory of fat solidification received support from the observations of Langer,⁷ who states that in young infants nearly all the fat in the body is concentrated into the panniculus adiposus, which is relatively nearly five times as thick as in adults. Langer found that when extracted from the adipose tissue the fat of infants did not completely melt below a temperature of nearly 40° C., so that the ordinary body temperature is not sufficient to keep it completely liquid. This much higher melting point of the fat of infants than of that of adults was found to be due to its containing a much larger proportion of stearin and palmitin, whilst the amount of olein was correspondingly less. There are, however, records of careful post-mortem observations of the skin and subcutaneous tissue of infants dying from sclerema which are not consistent with the above view, and which are equally difficult to reconcile with the clinical features and rapid recovery of such cases as have been quoted above. Thus Parrot⁸ found that the most conspicuous changes were atrophy of the skin and of the subcutaneous fat, and that in consequence of this latter change the fibrous trabeculae of the subcutaneous tissues appeared abnormally numerous and distinct. Ballantyne describes very similar appearances to those observed by Parrot, but he holds that the fibrous tissue increase is real and not merely apparent, and regards the atrophy of the fat cells as secondary to this sclerosis. Langer regarded the fall of the body temperature as the primary phenomenon and the solidification of the fat as the result of the cooling, but he suggests that in cases in which there is no conspicuous fall of temperature a similar result may be brought about by undue surface exposure to cold air or water. He quotes the observations of Sommer, who found that the natural temperature of new-born infants is somewhat higher than that of adults—viz., between 99.8° and 100° F. In cases in which there is a rise instead of the usual fall of temperature Langer ascribes the solidification of the fat to the oxidation and resorption of olein and a resulting elevation of the melting point. There is, however, another way in which we may look upon the relation of the lowered temperature to the sclerema. A conspicuous fall of temperature and early death are the phenomena observed in animals which have been varnished, and it seems at least possible that when the sclerema is universal or very extensive this affection interferes with the cutaneous functions, or more probably with the vaso-motor mechanism, in much the same way as varnishing does. It is true that Senator⁹ found, in the course of some experiments undertaken with a view to the reduction of fever by this means, that very extensive varnishing of the skin in human beings did not produce the effects which are observed when animals are similarly treated; but he attributes this to the fact that small animals have a greater surface in proportion to their bulk, and himself points out that children more closely resemble animals in this respect and are much more sensitive to surface cooling, and that therefore they would be more likely than adults to exhibit a conspicuous fall of temperature under such treatment. On such a hypothesis it is easy to explain the absence of conspicuous lowering of temperature in the cases in which the sclerema is limited to the dorsal aspect of the body. Since there is a tendency for the sclerema when once arrested to recede somewhat rapidly it seems possible that, provided adequate nourishment could be administered and if the warmth of the body were sufficiently maintained by placing the infant in an incubator, the time of most danger might be tided over, and recovery might result in some at least of the graver cases of sclerema neonatorum. All writers agree that external warmth is clearly indicated in such cases, and it sometimes has appeared to have very beneficial results.

In conclusion, a few words must be said about treatment by drugs. I have already mentioned that Dr. Angel Money

attributed much efficacy to the inunction of mercurial ointment in his case, for when this treatment was commenced the induration, which had up to then been extending, began to recede. When, however, we turn to Dr. Barlow's case we find that a similar arrest and recovery were observed although no mercurial treatment was employed; and in my case the improvement had certainly commenced during the week which preceded the inunction of mercurial ointment. After the mercurial inunction was stopped the improvement continued uninterrupted, but it is my impression that it was not quite so rapid as during the four weeks of mercurial treatment.

Chandos-street, Cavendish-square, W.

A CASE OF STRANGULATED OBTURATOR HERNIA IN A WOMAN AGED SEVENTY-EIGHT YEARS TREATED SUCCESSFULLY BY LAPAROTOMY.

By WILLIAM H. BENNETT, F.R.C.S. ENG.,
SURGEON TO ST. GEORGE'S HOSPITAL, AND EXAMINER IN SURGERY AT
THE UNIVERSITY OF CAMBRIDGE.

THE number of cases recorded of recovery after strangulated obturator hernia is comparatively small. The following case presents certain points of interest which seem to justify its publication.

A woman seventy-eight years of age was admitted into St. George's Hospital under my care on March 29th, 1895, with a history of having been fairly well, occasional attacks of colic excepted, until four days previously, when, after making a hearty meal of mutton chops, she was seized with violent gripping abdominal pain. Nausea followed almost immediately, and in a few hours vomiting set in. The vomiting continued up to the time of her arrival at the hospital, and for twelve hours it had been stercoraceous. No action of the bowels had occurred for four days. On admission the patient was emaciated and very feeble. There was a strong fecal odour about the breath; the face was "pinched" and had a marked "abdominal aspect." The pulse was weak, and the temperature subnormal. Acute intermittent gripping was complained of, principally below the umbilicus. There was an ill-defined desire to defæcate, but inability to do so. No blood or slime had been voided. The abdomen was only slightly distended, and upon manipulation violent, erratic, and painful peristalsis was excited. Examination by the rectum and vagina gave a purely negative result. Beyond the pain mentioned there was no other severe discomfort of any kind. As the case was clearly one of acute intestinal obstruction, and as no hernial tumour could be detected at any of the abdominal rings median laparotomy was performed at once. Upon opening the abdomen the small intestine as far down as the middle of the ileum was found to be distended; below that point the intestine generally was collapsed. The collapsed portion was traced down deeply into the left side of the pelvis, where it was tightly nipped under the arch of the pubes. Gentle and steady traction served to disengage a strangulated knuckle of gut about two inches and a half long, much congested and in parts ecchymosed; at one spot there was a laceration in the peritoneal surface surrounded by lymph. The damaged part was carefully cleansed and returned into the abdomen. No irrigation was used. Upon examining the left obturator foramen subsequently, it admitted readily the tips of two fingers, which passed through into a smooth sac of about the size of a pigeon's egg. The abdominal wound was united by fish-gut sutures in the usual way. Recovery followed and was uninterrupted. For the first two days there was some weakness, which rapidly passed off. The bowels acted with the aid of an injection of warm water on the fourth day after the operation; the stitches were removed on April 4th, and the patient left the hospital in her usual health on April 17th—i.e., less than three weeks after her admission.

It will be seen from a perusal of these notes that, as often happens in such cases, all the specific signs of obturator hernia mentioned in the text-books were entirely wanting in this instance. There was no fulness in Scarpa's triangle, the characteristic obturator nerve pain was absent, and nothing abnormal could be detected either by rectal

or vaginal examination. The symptoms were, in fact, merely those of acute intestinal obstruction, clearly due—judging from the characteristic, erratic, and painful peristaltic action—either to internal hernia, strangulation by a band, or to volvulus. The absence of distention after so long a period of strangulation and vomiting was a sure indication that the constricting medium was not of the sharp-edged kind. The diagnosis of obturator hernia was quite impossible, as is generally the case, although I mentioned it as being one of the possible conditions existing in the case before operating. The ease with which the hernia was reduced was—considering the time it had been strangulated—noteworthy, but was fully accounted for by the large and round-edged ring. Perhaps the most interesting part of the case is the recovery of a patient seventy-eight years of age after laparotomy under the circumstances described, especially when the damaged condition of the gut and the long period over which vomiting had extended are taken into account. Strangulated obturator hernia is very uncommon, and recovery after operation is rare. I have no recollection of any recorded case of recovery at so late a time of life as this patient's. Recoveries after laparotomy for the removal of ovarian tumours have of course been recorded up to a much greater age; but such cases, I need hardly say, are not comparable with a case like the one now described, in which the patient was suffering from the collapse entailed by strangulation of gut with peritoneal lesion, together with the exhaustion and depression caused by long-continued vomiting, which for some period had been feculent. The case affords, I venture to think, a striking instance of the great vital powers sometimes met with in old people who at first sight would appear to be too feeble to resist any great call upon their strength.

Chesterfield-street, Mayfair, W.

APOLOGIA PRO ELECTRICITATE SUÂ.

By W. S. HEDLEY, M.D. EDIN.

THOSE who have watched the solid, even brilliant, progress of electrotherapy in recent years acknowledge with regret and not without surprise that there is still a remnant of physicians who seriously doubt its capabilities, who refer to it as a "discredited agent," as something that has been tried and found wanting, or who, falling back upon a favourite phrase, express themselves as "disappointed in it." Of this remnant there is a certain minority even more aggressive in its attitude, more hostile in its scepticism. It is composed of those who roundly assert that neither does there exist any rational basis for the employment of electricity in medicine, nor is there any satisfactory demonstration of its curative effects; that once an agent of undoubted therapeutic promise, electricity now stands forth an admitted failure; that any good results that follow its use are due to psychical influence and rest on the baseless fabric of "suggestion." Scepticism of so pronounced a type is difficult of approach. It is useless to invite attention to the steady evolution of electrical methods in medicine made evident by the history of a hundred years; to point to that first period, the period of static electricity, which, broadly speaking, covered the second half of the eighteenth century, and is associated with the names of Jellibert, Mauduyt, and Bonnetoy; to that second period, commencing with the discovery of the "voltaic pile" (1800), associated with the names of Bischoff, Walther, and Most in Germany, of Sue, Thillaye, and Isnard in France; to that third period, the "period of the induced current," which, springing from Faraday's discovery of the phenomena of electro-magnetic induction (1831), ended with the brilliant work of Duchenne, to a period partly concurrent with the latter, represented by half a century of solid and lasting work bearing on the physiological effects and therapeutic action of the constant current, an epoch which recalls the names of Dubois-Reymond, Pflüger, Remak, Benedict, Brenner, Baierlacher, Ziemssen, Chauveau, Onimus, Legros, Boudet, and terminates about the middle of this century's "eighties" with the epoch-making works of De Watteville and of Erb. Approaching the present time, the apologist points in vain to the milli-ampèremeter, the voltmeter, the coulombmeter, to a period

of improved apparatus, of accurate measuring instruments, of modern currents—to a period, therefore, when the medical man finds himself in a position better than ever before to turn electrical energy into useful work. Equally useless is it, in presence of such a scepticism, to plead for electrical treatment that it ought to be judged by the same standards that apply to other remedial measures; useless to offer demonstrative evidence of the curative results that very constantly follow its efficient application, and to prove that as much at least is known of the nature of electricity and its way of working as is known of the action of many a drug that at the present moment holds an honoured place in the Pharmacopœia. The answer to such an appeal is a shrug of the shoulder or a shake of the head, with the inevitable reference to "suggestion" or "expectant attention." Now, this theory of "suggestion," associated mainly with the names of Möbius and of Rosenbach, may be briefly noticed. It announces the doctrine that electrification is merely a branch of psychotherapeutics, a doctrine which, shallow as it is and shortlived as it will doubtless prove to be, is nevertheless a form of heresy of a more or less seductive kind. Its little band of adherents ought to question themselves as to the reason for the faith that is in them. Before committing himself to such a belief the medical student, who is perhaps more than anyone else likely to be attracted by it, is reminded that in the first place he admits the effects of electricity to be physically and mathematically demonstrable, and in the second place he is aware that "suggestion" is as old as medicine, and that every drug has a psychical as well as a physical side to it.¹ He does not, however, say that because a bread pill may sometimes induce sleep if taken under the impression that it contains opium, that therefore opium acts by suggestion, neither does he say that because the actual cautery is sometimes successfully used in the treatment of hysterical paralysis that therefore the red-hot iron always acts by suggestion.² And from neuralgia he may learn a lesson. No doubt he is familiar with the fact that a neuralgia will often yield with surprising readiness to the galvanic anode; why in such cases, if the remedy act by "suggestion," does a change to the cathode increase the pain?³

The steady progress which a short historical survey makes evident need not obscure the fact that, whatever its position at present and whatever its prospects in the future, the use of electricity in medicine has undoubtedly had a chequered past. It has suffered by the activity of impostors, by the prejudices of its enemies, by the intemperate advocacy of its friends, and perhaps more than all by the crude empiricism of its methods. Those medical men who have attempted its employment have not always duly recognised the fact that the physical problem underlies the biological one, and that it is of vital moment to know something of the nature of the energy they employ. Until comparatively recent years this has scarcely been possible of electricity. Modern electro-therapeutics may in one sense be regarded as the practical outcome of those modern views which, inaugurated by Faraday and developed by his followers, have resulted in the electric dynamo, the electric light, the telephone, and many another application of electrical science to industrial pursuits. In point of fact, medical electricity "came before its time." It sprang from no solid basis of sound electrical knowledge. Carried away by the striking neuro-muscular phenomena that attend its application to living conductors, yet without any adequate knowledge of its physical nature, enthusiasts began to apply it *à tort et à travers*, without method and without measurement, and to all sorts and conditions of disease.

Medicine cannot reasonably cultivate an attitude of aloofness towards an agent to which it owes so much as it does to electricity. None deny that a fast increasing knowledge of neuropathology is largely due to electrophysiological research. Long ago it was pointed out that by the action of electricity on vital structures a surprising accuracy of diagnosis may often be arrived at, and that not only does it enable us to interrogate the neuro-muscular apparatus and ascertain the nature of a lesion, but sometimes even to foretell the duration of an illness.⁴ Electrical methods are now beginning to throw a not less important diagnostic light on a class of obscure gynecological cases where diagnosis is of vital moment, a diagnosis which "at one time will point to operative interference, at another will disarm the surgeon's

hand and show a conservative treatment to be not only possible but almost certainly successful."⁵ It is certain that in the use of the Faradic current of tension and of the galvanic current respectively, for the purpose of distinguishing inflammatory from non-inflammatory pain, gynecology has acquired a real addition to its diagnostic resources. To test the claims of electrical treatment it must be judged by the same standards that apply to the rest of medicine. What conditions is an accredited therapeutic agent expected to fulfil, and in which of these has electricity been tried and found wanting? Its physical and physiological effects are easily demonstrable. It is accurately measurable and under safe, easy, and complete control. Then comes the crucial question, Has electrical treatment made good its claim to curative power? Has it, when brought face to face with disease, had a success as constant and as clear as the average drug? A drug is looked upon as a curative agent because, other conditions being the same, effects follow its administration which without it would be absent. This "method of difference" in establishing the causality of an agent is sufficient for the ordinary affairs of life. Apply it to electrotherapeutics.

The three conventional forms of current hitherto used in medicine—viz., the galvanic, the faradaic, and the so-called "static"—are now supplemented, and to some extent supplanted, by electricity in certain new modalities. There are: 1. Those pulsatory currents produced by the electro-motive force of the ordinary constant current dynamo—currents which for medical as well as for other uses can now be turned on as required, like the water or the gas. 2. There are alternating currents of a more or less perfectly sinusoidal character, the frequency of which may vary from a few alternations to many hundreds or even thousands a second. The ordinary alternating light circuit furnishes a current of this order with a frequency of about 7000 to 10,000 alternations a minute. This as well as the constant current can be safely used through a resistance or a sliding shunt. 3. There are those oscillatory currents produced by the discharge of a Leyden jar, called by Dr. Morton (their discoverer) the "static-induced," which, although produced by an old and familiar apparatus, have every right to be ranked as modern currents. 4. There are currents of high frequency and potential, whose alternations may number hundreds of thousands, millions, or even exceed a billion a second.

1. With reference to currents produced by the constant current dynamo it is to be remarked that although "continuous" or "constant," and always flowing in the same direction, they are not absolutely uniform in strength. They are "pulsatory." They thus differ to some extent in physical nature from the current produced by the uniform electro-motive force of, say, a Leclanché cell. Small as this difference may be from an electro-therapeutic point of view, it must not be lost sight of. It is usually considered that with a 100-volt light circuit current passed through a controlling resistance pain is greater than when supply is drawn from a battery of low voltage. An explanation may perhaps be found in the physical character of the current rather than in its originally high voltage. The current controller or adaptor may be constructed on the principle shown in the following sketch, where A B is a fine platinum wire of

FIG. A.

suitable resistance with a sliding contact at X, which regulates the potential of the patient's circuit. By such an arrangement it is evident that any desired maximum or minimum of potential difference can be secured in proportion as the resistance between the runners (or the runner and the other shunt connexion) varies between zero and the total resistance of the wire. The variation of the difference of potential can be as slow and gradual as is desired. In practice the wire is coiled. The arrangement is, in fact, a "sliding shunt," and supplies, in the opinion of the writer, the best form of current controller or "reducer of potential" for adapting light circuits to medical use. An

instrument for the above purpose has lately appeared which, with many excellences, is not without faults. It consists of a rheostat having a total resistance of about 33 000 ohms, with a 16 candle-power lamp placed in circuit with each of the "leading in" wires "to protect the patient in the event of a short circuit." It has been pointed out in THE LANCET how futile is such a device. A lamp cannot be trusted to as a circuit breaker for medical purposes; it may allow twice its proper amount of current to pass before breaking. The magnetic cut-out⁷ is, so far as the writer is aware, the only arrangement yet suggested which can be seriously trusted to for the purpose in question; and even here it is to be remembered that the action is not quite instantaneous. In the adaptor under consideration there is also a third lamp arranged "in shunt" with the rheostat. The throwing in of this shunt reduces the voltage of the 115 volts circuit to 60 volts.

2. Of modern currents the one which will perhaps prove the most important for medical use is that form of alternating current whose curve is of the sinusoidal type. It takes its name from the fact that the current strength "follows the law of sines as regards its variation in time; it is a simple harmonic current"; a current which gradually attains its positive and negative maximum, shows no lost time and no actual interruptions. It is represented graphically by a curve of sines which may be contrasted with the very sudden and dissymmetrical changes of potential shown by the pointed curve of a coil's alternations. Inasmuch as the excitant action of an electric current bears a direct ratio to the suddenness of the fall of potential, it follows that the sinusoidal current will be better tolerated than the more brusque alternation of the coil. But on this very account it is equally evident that the latter for certain purposes can never be supplanted by the current in question.⁷ It appears by the researches of d'Arsonval that in the case of animals submitted to the action of sinusoidal currents an examination of the blood by the usual physiological methods shows a greater intake of oxygen and a greater output of carbon dioxide, a fact which of course in its turn points to increased metabolism throughout the body. A similar increase in the oxidation as evidenced by the increased excretion of urea has been proved by Gautier and Larat as the result of the therapeutic use of currents of alternating light circuits; but these are not of course strictly sinusoidal. They may be used through a rheostat and cut-out or by means of the sliding shunt already described. A small therapeutic alternator in which the rapidity of alternation is under the control of the operator furnishes in the experience of the present writer a current at once more useful and more easy to handle.

3. The so-called "static-induced" current is the direct product of the static machine with condensers. The patient is not insulated, however, but the connecting rods between the two Leyden jars are removed, the inner coatings are connected with the discharging rods, the latter being separated by a small spark gap.⁸ If, now, a rheophore held in each hand be attached to the outer coating of each Leyden jar it is evident that such an arrangement gives two circuits: one, the primary, includes the discharging rods, the spark gap, and the inner coating of the Leyden jars; in the other, the secondary or induced, there are the patient's body, the rheophores, and the outer coating of the jars. A current is thus obtained for which striking physiological effects are claimed; and certainly the ability to secure by its means powerful muscular contraction without pain is as wonderful as it is useful. More remarkable perhaps than the production of a new current from the static machine is the striking revival of an old one. The so-called electrostatic bath, with all its accompaniments and modifications, "soufflé," "douche," "frictions," exactly as described by Mauduyt and the pioneers of the eighteenth century, has once more vigorously pushed itself to the front. It consists, as everyone knows, of the simple placing of the insulated body in connexion with one pole of the static machine. In

explanation of the effects long known to follow its use it is now ascertained that this procedure produces well-determined effects, such as increased skin action effects on blood pressure, increase in the frequency and depth of the respirations, as well as (with the positive bath) an increased excretion of urea and of phosphates. Keeping in view the ever-changing electrical conditions of the air and the influence of the weather upon health, it is not impossible that "the electrics" of the atmosphere will eventually prove the key to treatment by the electrostatic bath.

4. Currents of high frequency and potential are generally obtained for medical purposes by means of the oscillating Leyden jar discharge traversing a solenoid. Such currents may carry energy enough to light a 5 candle-power lamp, and if the human body with its thousands of ohms resistance be at the same time placed in circuit there will scarcely be a perceptible diminution in the brightness of the glow; and yet, notwithstanding the tremendous amount of energy passing, there is scarcely a consciousness of its passage. Pain is absolutely absent. Why this harmlessness, whence this immunity from pain? Many theories have been advanced, all of them perhaps wide of the mark, but probably an inhibitory or "throttling" effect of the nature shown in an experiment shortly to be detailed enters into the question. Whatever the explanation, it is to be noticed that painlessness seems to be the great characteristic of all high frequency work. The physiological effects claimed as the result of passing these high frequency discharges through the body are many, but amongst the most noteworthy are (1) a considerable increase in the nutritive exchanges as evidenced by a greater absorption of oxygen and an augmentation in the carbonic acid exhaled; and (2) a vaso-dilator action on all the bloodvessels, resulting in a fall of blood pressure. Such currents are already emerging from the stage of experiment and promise, soon to bear fruit in actual practice. It is to be noticed that "rapid pure electric alternations" produce no excitatory action on the neuro-muscular apparatus, but seem to exert merely a paralysing or fatiguing influence, or what has been termed a "throttling" effect on the passage of another stimulus. The recent experiment of Lodge and Gotch, which points to this conclusion, is as follows: Taking the physiological limb and applying a stimulus of a rapidly alternating character directly to the nerve, "at the same time as some other well-known one-hundredth volt, stimulus is applied to another part of the same nerve farther from the muscle; it can be shown that rapid electrical alternations, if entirely unaccompanied by static charge or by resultant algebraic electric transmission, evoke no excitatory response until they are so violent as to give rise to secondary effects such as heat or mechanical shock. Yet notwithstanding this inaction they gradually and slowly exert a paralysing or obstructive action on the portion of the nerve to which they are applied, so that the nerve impuler, excited by the feeble, just perceptible, one-hundredth volt stimulus above, is gradually 'throttled' on its way down to the muscle, and remains so throttled for a time varying from a few minutes to an hour after the cessation of the violence."

Turning from this the most modern of currents to that which is the most ancient, the familiar spark of the so called static machine, the attention is arrested by a striking difference. That excitatory action so completely absent in the former is in a marked degree present in the latter. Apart, however, from this great physiological difference the current of pure rapid electric alternations and the static spark have many points in common. Each static spark seems single, but it in reality passes backwards and forwards hundreds of thousands of times. It oscillates, each oscillation growing less and less until the conductor is discharged. It is not to the conductor, however, that attention ought to be directed, but rather to the surrounding medium, to the electrostatic field, to the dielectric strained by electromotive forces, and the insulating power of the air eventually breaking down under the electric stress or tension. At the same time from the discharging circuit "waves of electrical distortion," to and fro disturbances of the ether, spread and radiate in all directions. This is the genesis of what are known as oscillatory currents, currents which are for the most part sinusoidal in character. In all electrical work it is instructive to transfer the attention from the conducting wires to what is going on outside them and to picture the ether disturbed by electromotive forces propagating the disturbances by undulatory or wave movement, until the energy becomes dissipated or taken up by some

⁶ THE LANCET, April 9th, 1892.

⁷ The subject of coils cannot here be entered upon; it is sufficient, however, to remember that the modern instrument furnishes currents of a range and quality far superior to those of the "haradic machine" in ordinary use in this country. This superiority is secured not only by the number and variety of the windings of the secondary coils, but by the nature of the interrupter, which is not a vibrating one and has a separate source of supply to "action" it. The result of such arrangements is that not only is irregularity in action avoided, but a range of rapidity of alternation is obtained varying from the slowest rate (for muscular action) to 30,000 a minute for sensitive effects.

⁸ In practice the circuit is usually broken by a special electrode.

suitable appliance and utilized for work. The energy, however, does not, according to "modern views," travel by the conductor, but through the insulating medium, or dielectric. The conductor, whether it be a wire or a living body, only guides the energy and concentrates it for useful work. Applying this to that very imperfect conductor, the human body, it is evident that the latter may be regarded as an appliance capable of utilising in a variety of ways energy transmitted by the ether. It resembles an ordinary metallic conductor in that it guides the effects transmitted by the ether contained in the dielectric, but it differs from the wire in the fact that the guidance is probably effected by that peculiar form of conduction known as electrolytic; and this leads up to the infinitely important point that electrolytic conduction is probably "invariably accompanied by decomposition, and only occurs by its means." Further, Helmholtz has shown that "the most infinitesimal electromotive force is sufficient to effect its due quota of decomposition." From a different standpoint it may be allowable to think of the ether vibrations springing from some electrical source as impulses communicated, motion added, to the already pulsating atoms of a vital structure. Giving further play to such a train of thought, it is possible to imagine certain of the delicate mechanisms of the human body as "receivers" syntonised for the reception of similarly vibrating ethereal impulses radiating from some given source. The relationship of physiology with physics is strongly brought out in a theory (whether it prove right or wrong) recently suggested by Professor Lodge. It is found that a tube of metallic filings—i.e., a series of loose contacts—diminishes its electrical resistance when exposed to "even the distant neighbourhood of a Leyden jar or coil spark." Such an arrangement is called by Lodge a "coherer," and he suggests that perhaps the eye acts on such a principle. He "wishes to guess that some part of the retina is an electrical organ, say like that of some fishes, maintaining an electromotive force which is prevented from stimulating the nerves solely by an intervening layer of badly conducting material with gaps in it, but that when the light falls upon the retina these gaps become more or less conducting and the nerves are stimulated." This is the so-called electrical theory of vision, and to Professor Lodge, and to him alone, is due the merit of having suggested it. Although the nature of the action of the eye as a detector of radiation is still little better than a guess, it cannot be said that there is anything extravagant in the idea that the hexagonal pigment cells or the rods and cones of the retina act, under the impulse of those ether vibrations which constitute light, in a way almost identical with the action of a coherer. It seems even conceivable that other histological arrangements—e.g., those nerve fibrils which conduct yet only touch and do not anastomose, those motor nerve endings which are only in contact with the sarcoous substance; indeed, any conducting arrangement in the animal body which may be classed as a "bad contact"—may constitute the physiological analogue of what would be electrically known as "a coherer."

Descending from the region of wild dreams and speculations, many of which are still immeasurably short even of the experimental stage, and reverting to a sober survey of medical currents, the attention is arrested by the want of uniformity in their designations. A new nomenclature seems desirable and almost necessary—a nomenclature in which electrical currents for medical purposes can be distinguished by their physical character rather than by the name of a discoverer or the mode of their production. Such a classification has recently been formulated by Professor Houston and Mr. Kennelly, two distinguished physicists to whom electro-therapeutics is already under many obligations. It is pointed out that medical currents can be referred to four main types—viz., continuous, alternating, intermittent, and convective. These are subdivided as follows:—1. Continuous currents may be (1) uniform and (2) pulsatory. The former class is produced by a uniform electromotive force, such as that of a Leclanché cell, and would comprise those currents at present known as galvanic. A pulsatory current is, as already stated, continuous, and always flowing in one direction, but not uniform in strength. Such a current is produced by the constant current dynamo. (Fig. B.) 2. Alternating currents—that is, currents which periodically reverse their direction—may be symmetrical or dissymmetrical; the symmetrical may be sinusoidal (Fig. C) or non-sinusoidal (Fig. D). The electromotive force of the

former is represented by a curve of sines. In a non-sinusoidal alternating current the positive and negative maxima are equal but not smoothly attained, and the graphic representation is of a more or less angular, not of a wavy, character. Voltaic alternating currents are of this type. The most familiar example of the dissymmetrical alternating current is that produced by the ordinary medical induction coil. (Fig. E.) Intermittent currents are oscillatory and non-oscillatory. "An oscillatory current is an alternating current, usually sinusoidal in type, but decaying in amplitude—i.e., each wave is smaller than the preceding one.

FIG. B.

FIG. C.

Oscillatory currents produced by the discharge of a Leyden jar correspond to the 'static induced.' They are usually of extremely brief duration and of very high frequency, a whole series of perhaps ten oscillations being completed in, say, the 20,000th part of a second. Non-oscillatory intermittent currents are produced by the discharges of influence machines through circuits unfavourable to the

FIG. D.

FIG. E.

Figs. B., C., D., E., are after Houston and Kennelly.

development of oscillations. Franklinic currents are of this nature. Convective currents or convective discharges are produced by the convection of electrified particles of air or other material (the static breeze).¹⁰ The classification thus detailed is as follows: (1) continuous current—(a) uniform, (b) pulsatory; (2) alternating—(c) sinusoidal, (d) non-sinusoidal, (e) non-symmetrical; (3) intermittent—(f) oscillatory (g) non-oscillatory; (4) convective—(h) static breeze. Such a nomenclature may require modification, but it is very practical and possesses the great advantage that in the selection of a current for medical purposes the name points directly to its physical character, and in some measure, therefore, to the therapeutic indication it may be expected to fulfil.

Looked at from the standpoint of modern practice, the field of electro-therapeutics seems broadening. No longer limited to strictly local applications, it now embraces those procedures whose aim it is to influence, and which demonstrably can influence, the entire economy. Its object is so to utilise electro-physiological data as to influence innervation, heart action, muscular conditions, respiration, temperature, the oxidations, every functional action and metabolic charge, and not least by the process darkly known as "vaso-motor influence" to modify and control the blood-supply to organs and tissues. There are times when the power of electrification to reach an internal organ will depend not on any direct action inherent in an electric current, but on an influence which, having its starting point in the electrical stimulation of some surface area, and travelling perhaps *via* nerves of common sensation, will strike the spinal cord at some special spot, and reflected thence will find a route by filaments of the sympathetic to some particular organ, an organ thus in neural relationship, through this special segment of the cord, with that area of cutaneous surface which was the site of the electrical stimulation. Such a process not only throws light on the rationale of peripheral electrical excitation, and especially of the action and uses of the faradaic brush, but is

⁹ Lodge: Modern Views, p. 79. Macmillan and Co.

¹⁰ Houston and Kennelly: The Polyclinic, September, 1894. New York.

one of the many points which, if duly weighed, tend to a wider conception of the entire question of treatment by electrical methods. To "kick up" a set of sluggish muscles into action, to stimulate, if such expressions be allowable, the neuro-muscular apparatus into a display of electrical gymnastics, can no longer be considered the sole aim and object of electrification. Such effects doubtless rank amongst the most striking and valued effects of electric currents, but cannot in the presence of those varied and far-reaching influences of the kind that have just been considered any longer claim exclusive possession of the field. The latter view begins now to be clearly reflected in practice. The revived use of the electrostatic bath, the methods of central galvanisation and of general faradisation, and general applications to the entire body by means of the water bath through which sinusoidal or other currents are passing, are procedures which seem to be supplementing and in some measure displacing the more strictly localised forms of application; and now that it is known how to obtain currents of high frequency and potential, and that it has become possible to demonstrate the physiological qualities that belong to them, it becomes probable that there will soon be the opportunity to realise in practice the therapeutic effects not only of passing these high frequency discharges through the body, but of subjecting it without contact with the terminals to a kind of electrical bombardment in the rapidly alternating electrostatic field between them. This is new ground: once broken, it is likely to prove a wide and fruitful field. Progress in this direction is rapid and striking. France, America, and Germany are at the present moment each the active centre of an onward movement in electro-therapeutics, a movement which experimental investigation, clinical observation, and organised association go hand-in-hand to accelerate and to strengthen. Another mark of progress appears in the fact that physiologists begin to recognise that chemical and electrical processes are inseparable from those that have hitherto been called vital, and that electromotive force is very constantly the outcome of physiological action. There are signs that physics begins to "encroach on the domain of physiology and that medical men are more and more turning their attention to physics."¹¹ What has been called "physical biology" or "biological physics"¹² seems already beginning to differentiate itself and to stand out as a special branch of science. It forms a kind of neutral ground where medical and electrical science find a common holding point and a common end. To the medical man his line is clear. With the lessons of experience well in view, he takes his stand upon the broad principles of electro-physics and the known action of electrical currents on vital structures. When such indications fail to guide him and fail they often must, he will not on that account fold his arms in helpless inaction, but falling back upon an enlightened empiricism he will gently feel his way. He will "not ask, but try." He will not be afraid to acknowledge that after all is said therapeutics is to a large extent but a process of cautious experimentation.

Brighton.

HEPATIC ABSCESS FOLLOWED BY AMOEBIC DYSENTERY: OPERATION; RECOVERY.

By JOHN CURNOW, M.D. LOND.,

PROFESSOR OF ANATOMY IN KING'S COLLEGE, LONDON; PHYSICIAN TO KING'S COLLEGE AND THE SEAMEN'S HOSPITALS.

THE following case is of special interest as demonstrating the causal connexion between dysentery and the so called tropical abscess of the liver. In almost every case of hepatic abscess which I have seen at the Seamen's Hospital during the past ten years there has been a history of an antecedent attack of dysentery, but this is the first case in which the causal connexion has been so definitely proved. Murchison's great authority is always quoted against this view, but he seems to have based his conclusions on the statistics of Indian observers rather than on his own experience. The migration of the amœba coli from the intestine to the liver must now take the place of chill, excessive eating and

drinking, tropical climate, and other vague generalities to which tropical abscess is so frequently ascribed. Amœba coli have been found in the pus of a liver abscess by many observers, and also in the dysenteric stools at the same time by pathologists in Germany and in America; but so far as I am aware this is the first occasion in which their coexistence has been demonstrated in this country.

The patient, a Lascar aged forty-two years, was admitted to

the Seamen's Hospital, Greenwich, on Dec. 22nd, 1894. On admission he complained of pain in the right side of the chest, cough, fever, and a feeling of general illness for one week. His general health had been good, and he had had no serious illness. In June, 1893, while in Calcutta, he had an attack of dysentery with some tenesmus and tormina, and passage of blood and mucus. He got quite well in about twelve days, and since then had not been similarly affected,

his health being fairly good. He was taken ill with the present attack while on board his ship in the West India Dock. He complained of a constant dull aching pain in the right side and some cough; these symptoms gradually became worse in the course of a few days. On examination he was found to be a poorly nourished man, with an anxious expression and slightly accelerated breathing. There were signs of fluid in the right pleura

¹¹ D'Arsonval, Académie des Sciences, Paris, 1893.

¹² Ibid.

from the angle of the scapula downwards; there were a few scattered catarrhal sounds in both lungs. The heart's apex was beating in the fifth intercostal space, half an inch outside the nipple line. The sounds were healthy. Liver dulness began above at the sixth rib in the nipple line, while behind and in the axilla the upper border of the dulness was indistinguishable from that due to the fluid in the pleura. The edge of the liver could not be felt below the costal margin. There was no obliteration or bulging of the lower intercostal spaces on the right side, but there was slight tenderness on pressure over the liver, and some pain on deep inspiration. The bowels were regular, and the stools normal. The tongue was slightly furred. The temperature (see chart) varied between 100° and 101.8° F., the diurnal variation being about 1°; there were no rigors, but there were occasional irregular sweatings. The condition of the patient began to get worse and the pain in the right side more severe. The right pleura was aspirated on three occasions in different situations, but only ten ounces of clear straw-coloured fluid were withdrawn, after which, however, the signs of fluid disappeared, so that it was thought there had been only a thin layer of fluid lying over the base of the right lung. The position of the heart's apex remained fixed. Aspiration did not improve the condition of the patient, the temperature still remaining high. It was thought very probable that there was an abscess in the liver, and so it was decided to explore that organ if the patient did not improve. On Jan. 13th, 1895, three weeks after admission, the patient had a very severe attack of pain in the right hypochondrium, so the liver was at once explored. From the second puncture some thick, sweet-smelling chocolate-coloured pus was withdrawn. Next morning Mr. W. Johnson Smith, F.R.C.S.,

Specimens of the pus were frequently examined upon the warm stage, but very accurate observations were not easy on account of the density of the pus and the great number of other elements besides the amoebæ. The shape of the living amoebæ was very various and irregular, the commonest variety being oval or pyriform. The outline of every amoeba was very distinct, giving the appearance of a dense investing or limiting membrane. The most noticeable feature was the presence of vacuoles of various sizes, one being commonly noticed to be much larger than the rest. The division of the body of the amoeba into an ecto- and endo-sarc was sometimes noticed, though rarely; this distinction was more marked in the stained preparations. The ecto-sarc was seen to be quite clear and highly refractile, while the endo-sarc, in addition to the vacuoles, contained several blood-corpuscles, resting on a groundwork of granular material. The size of the resting amoebæ was very variable, ranging, in oval organisms, from a long diameter of 70 μ to 20 μ , and a transverse diameter of about 15 μ to 20 μ . The round amoebæ had in most instances a diameter of 20 μ to 30 μ . In some of the amoebæ as many as sixteen to twenty red corpuscles were seen, some retaining their yellow colour, while others were quite devoid of pigment, looking like round or oval colourless discs, in many cases overlapping each other. In the fresh specimens a nucleus was only rarely seen, and then with difficulty. On the warm stage some of the amoebæ were in active movement, altering their position from time to time. These movements were effected by the throwing out of pseudopodia, which became fixed, and the body of the amoeba then merging into the processes which had been thrown out. These pseudopodia were of various lengths, the majority being short, thick, and with round, blunt extremities. No move-

removed about an inch and a half of the seventh rib, lying midway between the nipple and anterior axillary lines. When an incision into the liver was made a large quantity of pus, similar to that removed by the exploring needle, escaped. The abscess was situated in the convex portion of the right lobe, lying fairly superficial, and, as far as could be judged by the finger, of large size. The limits of the cavity could be made out in all directions except upwards and backwards, where the point of the finger reached a small opening, leading presumably into another abscess cavity. A large drainage tube was inserted and the patient sent back to bed. After the operation the general condition of the patient began to improve, but his temperature became higher and more irregular. There was an abundant discharge of pus, at first chocolate-coloured and rather like anchovy sauce, but later it became more healthy and yellow in appearance. The wound was dressed frequently, and the cavity washed out once daily with a weak solution of iodine water, whereupon it quickly began to diminish in size. As the temperature was still high and irregular the right pleura was again aspirated, and nine ounces of clear fluid were withdrawn, with the effect of restoring the pulmonary resonance, and allowing some rough friction sounds to be heard. Three days after the operation the patient had a sharp attack of dysentery, lasting about ten days, which yielded to a daily irrigation of the rectum with a weak solution of quinine, a pill containing mercury, ipecacuanha, and opium being given internally. The temperature came down finally on Feb. 1st, and he made an almost uninterrupted recovery; on April 21st the wound had completely healed, and he was quite well.

Remarks.—The main point of interest in the case, apart from the recovery of the patient, is the discovery of the amoebic dysentery in the pus, from the liver, and in the evacuations.

ments of the protoplasmic granules were noticed. A large number of stained preparations of the hepatic pus was made, the following being the method employed. Some pus was shaken up in a test-tube with five or six times its volume of logwood stain diluted to a claret colour and containing, as a preservative, 1 per cent. of hydrocyanic acid. This was shaken occasionally for two days, and after the pus had settled to the bottom of the tube the clear stain was decanted off, and the residue was washed with camphor water. Some glycerine was poured into the tube and collected at the bottom, into which the stained pus was allowed to settle, and was then ready for mounting. For mounting preparations in Canada balsam the same method was adopted, only that after the pus had been stained and washed it was dehydrated by alcohol, cleared by setting in coal-tar naphtha, and then mounted. In the stained preparations the details of the amoebæ could be more accurately made out than in the fresh specimens. In almost all amoebæ the nucleus was prominent and deeply stained. Besides a large number of red blood-corpuscles and the granular groundwork of the organism numerous cells with deeply stained nuclei were seen and taken to be pus cells. Another interesting feature of the case was the attack of dysentery from which the patient suffered three days after the opening of the liver abscess. Since the first attack eighteen months previously the patient had had no return of the dysentery, so that it is possible that the opening of the abscess which again started the dysentery. The stools were examined microscopically, and besides numerous blood-corpuscles a few dead amoebæ were seen, all of them having a circular outline. The facts that amoebæ were found, although in small numbers, in the stools, and that the dysentery yielded so readily

to large rectal injections of quinine, seem to show pretty clearly the relation of dysentery to liver abscess and of the amoeba dysenteriae to both affections. The length of time from the primary outbreak of dysentery to the onset of symptoms pointing to hepatic abscess is also worthy of note. The diagrams well show the appearance of the amoebae seen under $\frac{1}{2}$ th objective oil immersion, and they were drawn, with the aid of a camera lucida, the exact size as seen under that power. The relative sizes of a pus corpuscle and red blood-corpuscles are also shown. I am indebted to my house physician, Dr. C. W. Windsor, for the history of the case, and I have to thank Mr. Hart, the dispenser at the Seamen's Hospital, for the trouble which he has taken in staining, mounting, and watching the amoebae.

Wimpole-street, W.

CONTRACTED ELBOW, WRIST, AND FINGERS FOLLOWING PRESSURE ON MEDIAN NERVE BY SCAR TISSUE.

NERVE FREED BY OPERATION; SUBCUTANEOUS SECTION OF ALL THE FLEXOR TENDONS AT WRIST; COMPLETE RESTORATION OF FUNCTIONS OF THE HAND.¹

By A. H. TUBBY, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE WESTMINSTER HOSPITAL; SURGEON TO OUT-PATIENTS, EVELINA HOSPITAL FOR SICK CHILDREN, ETC.

THIS case is of considerable surgical interest on account of the cause of the contraction and its duration, the difficulty of finding the site of lesion of the nerve, and the extensive dissection required; but chiefly it is of value as showing that clean division of all the tendons on the flexor aspect of the wrist gives a satisfactory result, and that both flexion and extension of the fingers can be fully restored after so radical a procedure. The details of the case are as follows.

A girl aged four years was brought to me at the National Orthopaedic Hospital on Oct. 20th, 1893, with the history that one year previously she injured the front of the right forearm. She was taken to the German Hospital; but beyond the fact that splints were applied and that subsequently some matter came from the forearm, no further details could be obtained. On examination the right elbow was found to be partially flexed, the forearm fully pronated and the wrist flexed, the thumb and first and second fingers were forcibly bent into the palm, and the third and fourth fingers less so. Sensation was impaired in the outer part of the palm and on the palmar aspect of the thumb and first and second fingers. There was, however, no glossiness of the skin and the nails were intact. On attempting passive movement it was found impossible to either supinate the forearm or extend the wrist, thumb, and first and second fingers, but the third and fourth fingers could be passively moved through an angle of about twenty degrees. About one inch below the bend of the elbow and in the middle line, at the anterior aspect of the forearm, a depressed scar half an inch in diameter was seen. It was somewhat firmly adherent to the deeper structures. Judging from the appearances presented by the limb I thought the history of the case might be somewhat as follows:—Injury to the upper end of the ulna, followed by suppurative and pressure either of a small amount of callos or scar-tissue on the median nerve just after it had passed through the two heads of the pronator radii teres. This idea received confirmation on writing to the German Hospital. In the reply to my letter the house surgeon kindly gave the following details. The patient was admitted on May 20th and left the hospital on June 12th, 1893. The history of the accident was that the child had received a blow on the anterior part of the forearm, which caused a fracture of the coronoid process of the ulna accompanied by considerable bruising. Suppuration had followed, and when the wound had healed the forearm was seen to be flexed and pronated, and the wrist could not be extended. The child was taken into the National Orthopaedic Hospital, and for a month douching with hot and cold water, friction, passive movements, and galvanism were persevered in, but no improvement was noted. I then decided to operate hoping to find the nerve lesion in the

neighbourhood of the elbow-joint. I commenced my incision just above the bend of the elbow and in the centre of the flexor aspect, and carried it towards the hand for four inches. The median nerve was found at the bend of the elbow and traced downwards between the heads of the pronator radii teres until it disappeared beneath the flexor carpi radialis; but it was quite healthy in this region. The incision was then lengthened for two inches and a half, and the flexor carpi radialis cut through at its centre and the ends turned upwards and downwards. The opportunity so afforded was now taken to examine the anterior interosseous nerve in a part of its course, but that, too, was healthy. The median nerve was still further traced out and at two inches and a half above the wrist was found to enter a mass of dense scar tissue. When freed from this the nerve trunk was opaque in colour for an inch of its course and shrunken to half its natural extent. The scar tissue was carefully removed, the two portions of the flexor carpi radialis united by gut sutures, and the wound closed, a few threads of horsehair being left in the centre to serve as a drain. This drain was removed on the fourth day, when it was found that primary union had taken place. At the end of the tenth day all the sutures were taken out as the edges were firmly united. The results, two months afterwards, were that supination and extension were much increased, doubtless owing to division of the flexor carpi radialis at the operation, but the movements of the fingers and wrist were not much improved. It was, therefore, decided to divide the flexor tendons of the wrist. This I proceeded to do by prolonging the former incision to the junction of the forearm and hand, finding the median nerve, and passing a blunt-pointed tenotomy knife underneath it. I cut firmly downwards towards the bone, dividing every tendon which offered any opposition to extension of the fingers and thumb. I think that the palmaris longus, the flexor sublimis and profundus digitorum, and the flexor longus pollicis tendons were completely severed. No attempts were made either to bring the divided ends into apposition nor to unite the proximal to the proper distal parts. The hand and fingers were placed upon a malleable iron splint in the position they occupied before the second operation—that is, the wrist and fingers fully flexed. In ten days' time the splint was removed and the wound was found to be soundly healed. The forearm and hand were then placed in a gauntlet of plaster-of-Paris, with the wrist flexed and the fingers and thumb bandaged into the palm. At the expiration of ten weeks after the operation, gentle extension of the fingers and thumb was begun, and the movement gradually increased till full extension could be obtained. The child was sent out of the hospital wearing a plaster-of-Paris gauntlet, which still kept the wrist flexed, but left the thumb and fingers free. At this time considerable active movement had returned to the hand. For a further period of six months the gauntlet was worn, the little patient coming up twice a week for friction and galvanism.

Result.—A year afterwards the movements of the right forearm and hand were completely restored and the parts were in good position. She could use a knife and a spoon well, write on a slate, and pick up small objects from the table, such as a pin.

Remarks.—The history and the position of the scar were particularly misleading in this case. The nerve lesion was found at a distance of three inches from the superficial scar. It appeared to me that considerable suppuration must have taken place in the forearm, the pus burrowing towards the hand and pocketing around the nerve. The spot where the latter was compressed was probably the farthest point of the pocket. It was the uncertainty at the time of operation as to the exact site of the nerve lesion which led to such an extensive dissection of the forearm; the large wound, however, healed perfectly. It might be questioned if it would not have been sufficient to have divided the flexor tendons in the first place without seeking for the point of pressure on the nerve. This in itself would have been an unsurgical proceeding, and it seems to me that no active flexion of the fingers could have been expected with the nerve pressed upon as it was by dense scar tissue. The complete restoration of active movement is a sufficient proof that the functions of the nerve were in abeyance owing to pressure. That more complete movement was not obtained after the first operation was, I take it, due to the adaptive shortening of muscles and tendons which followed the flexed position of the hand and fingers arising from irritation of the nerve. Mere freeing of the nerve was not

¹ Communicated to the British Orthopaedic Society, Jan. 31st, 1895.

sufficient to correct this, although some immediate improvement resulted. With reference to the important question of section of the tendons of the wrist-joint, this example shows that it can be done with impunity, and even with success. Although no efforts were made to bring the severed ends into apposition, yet perfect union took place. One is aware how often it happens that if the tendons be severed by broken glass or any other accident non-union results. In this case the utmost care was taken to keep the wrist and fingers flexed for ten weeks after the second operation, so that by these means the uniting material became firm. Some experiments² I made on division of the tendo Achillis of rabbits convinced me of the necessity of great care in avoiding premature stretching of the uniting material of divided tendons. I have known it to continue to stretch for fourteen months after the date of operation. Therefore in this case the wrist was kept slightly flexed for a whole year after the second operation. To the fact, then, that the extensors were prevented from pulling upon the weak uniting material of the flexors at the wrist I ascribe in a large measure the complete restoration of the functions of the hand.

Finsbury-circus, E.C.

A CASE OF PSEUDO-HYPERTROPHIC PARALYSIS WITH THE KNEE-JERKS PRESERVED.

By W. S. COLMAN, M.D., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE HOSPITAL FOR CHILDREN, GREAT ORMOND-STREET; REGISTRAR TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

THE following case of pseudo-hypertrophic paralysis presents several unusual features and seems of sufficient interest to be placed on record.

A boy aged ten years was brought to me at the Hospital for Sick Children, Great Ormond-street, on Dec. 29th, 1894, with the following history. He had been quite well and strong, and as forward as other children, till he was five years old, when it was noticed that he was "weak on his legs" and that his calves were unduly large. This weakness continued to increase, but very slowly—so slowly that he was active and could run, play football, &c.—until a year before he came under observation, when he had a severe attack of scarlet fever, and after this he became rapidly weaker, and his football performances were confined to keeping goal. The arms were now noticed to be getting weaker, so that he had difficulty in holding the brush when blacking his boots. He was born at the full term and was a perfectly healthy infant; he walked at sixteen months and could talk when two years old. Beyond the attack of scarlet fever mentioned above he never had any illnesses. His head was "funnily shaped" from birth. The family history revealed nothing important. A brother twelve years old had broken his left arm on two occasions and his right leg once, but presented no other signs of disease. On examination the patient was found to be a rather thin but active-looking boy. There was an obvious prominence on the forehead along the line of the frontal suture, and the skull presented a well-marked scaphoid shape. His intelligence and degree of education were fully up to the standard. He walked with an awkward and rather high-stepping gait. When his feet were off the ground they showed a well-marked "pes cavus" deformity, which disappeared when he stood erect. There was commencing slight contracture of the gastrocnemii on both sides. On examination of the muscles there was great enlargement with weakness of the gastrocnemii and of the vasti externi—the crureus and vastus internus being but little affected on each side. The glutei were very little enlarged. The muscles in front of the leg were little affected. An electrical examination showed over-excitability of the gastrocnemii and vasti externi to stimulation by a faradaic current, a current too weak to produce contraction in a healthy child at once causing a contraction in these muscles, and the reaction was greater on the left side, on which the hypertrophy was also most marked. The reaction of the other muscles to the faradaic current was normal. To the constant current all muscles responded normally. In the upper limb there was considerable weakness of movements

about the shoulder. The deltoids and triceps were enlarged, and notably the infra-spinati on each side. There was some wasting of the biceps, pectorales, latissimus dorsi, and of the muscles of the thumb. The muscles all responded readily to both forms of electrical stimulation. Sensation to all forms of stimuli was normal in all parts. The knee-jerks when he was first seen were extremely active, but after he had been under observation six weeks they became much more moderate. Ankle clonus was not elicited at any time. During the last few months he has had slight difficulty in controlling micturition, and had wetted the bed on several occasions. He had retained control over the sphincter ani, but had to obey any calls very promptly, any hot drink producing a rather loose action of the bowels almost immediately. In all other respects he appeared to be quite healthy.

The chief points of interest are the small number of muscles affected although the disease had been recognised for five years, the retention of the knee-jerks, and the electrical reactions. The preservation of the knee-jerks at so late a period of the disease is so unusual a condition that I have been unable to meet with any recorded case. In this case there seem two possible explanations. The first—to which I incline—is that it was owing to the fact that, although the vastus externus was extremely enlarged, no change could be observed in the vastus internus, whose electrical reactions also corresponded to those of unaffected muscles. It has been shown by Professor Sherrington¹ that the vastus internus is the essential muscle for the production of the knee-jerk. The nerves to the other constituents of the quadriceps may be cut in an animal, but if the nerve to the vastus internus is uninjured the knee-jerk will be elicited as before. In the case of my patient I attribute the retention of the jerk to the escape of the vastus internus, and expect that as soon as that muscle becomes invaded the knee-jerk will disappear. The other possible alternative is that there may be some coexistent gross spinal cord disease; but of this not the slightest evidence could be discovered except the very doubtful evidence from the weakness of the sphincter muscles. The curious over-excitability of the enlarged muscles to faradism is a phenomenon that I have observed before in at least one case of pseudo-hypertrophic paralysis, and presumably is due to an abnormal excitability of unaffected fibres in the muscle, and may indicate some change in the muscle fibres immediately preceding the atrophic process.

Wimpole-street, W.

A CASE OF PULSATING EXOPHTHALMOS.

By ADOLPH BRONNER, M.D.,

SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL, AND LARYNGOLOGIST TO THE BRADFORD INFIRMARY.

THE patient, a married woman aged thirty-six years, saw me on Oct. 23rd, 1894. For five weeks she had had severe "neuralgic pains" in the right side of the head, more marked near the temple. Four weeks ago (one week after the commencement of the pains) she heard a pulsating noise in the right side of the head, accompanied by severe throbbing pains; and she had also noticed that the right eye had become prominent. The pain, noises, and protrusion of the eye were at first very slight and had gradually become worse up to one week before I saw her. During the last week they had remained stationary. When she was excited or bent the head the noises and protrusion became more marked. The patient was a pale, weakly woman and looked fifty years old. The right upper lid drooped, was swollen and tense, with thick veins, and covered the eyeball. The lid could not be lifted up. A thick fold of dark-red conjunctiva protruded between the lids and was larger on the inner side. The lower lid was also swollen. The eyeball protruded forwards and outwards, was divergent, and could not be moved. No pulsation of the eyeball could be seen or felt when the patient was quiet. As soon as the head was bent a slight pulsation was noticed. The eyeball could be pressed back into the orbit to some extent. The conjunctiva bulbi was thick and red and contained many dark veins which converged towards the cornea. On the inner side of the eye there was a soft tumour which seemed to press

² Guy's Hospital Reports, 1891.

¹ Journal of Physiology, vol. xiii.

the eye forwards and outwards. The iris was slightly discoloured; the pupil was large and acted very slowly to light. There was a slight deposit of semi-transparent lymph on the anterior capsule of the lens. The fundus was slightly hazy. The veins were extremely swollen and dark, with peculiar constrictions which gave the appearance of a string of sausages. The disc was slightly congested and the edges slightly blurred. Vision = $\frac{1}{2}$. There was pulsation of the retinal veins. A loud, intermittent, blowing noise could be heard with the stethoscope on the whole of the right side of the head, being most marked over the orbit and temple. On pressure on the internal carotid the noises nearly ceased. The patient was kept in bed for some days. The pain slightly decreased, but otherwise there was no improvement. On Nov. 8th the internal carotid was tied. The noises at once ceased; there has been no pain since. The exophthalmos

into the cavernous sinus. 3. The communication must have been at first small and gradually become larger, as the protrusion of the eyeball increased for three weeks, and as there was no history of a sudden violent pain or sudden intense noise. 4. The vision was fairly good; there was no marked papillitis. This proves that there must have been a free anastomosis between the central retinal vein and the inferior ophthalmic veins. 5. There was no pulsation except when the patient bent the head. This is the second case of pulsating exophthalmos which has come under my notice; the first case is recorded in the Transactions of the Ophthalmological Society, vol. ix.

Bradford.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF EMPYEMA OCCURRING IN A VERY YOUNG CHILD.

BY MALCOLM MACKINTOSH, M.D. GLASGOW.

THE child in question was a female aged four weeks and four days who was found dead in bed beside its mother at an early hour on the morning of April 5th last. The parents are healthy, and the baby, who was born at full term after an easy confinement, showed no sign of anything abnormal. It was fed at the breast and never had any difficulty in taking its food easily and naturally. The mother noticed nothing worthy of remark until the evening before the child died, when she observed that it gasped several times in a way that she had not noticed before; but on referring to the nurse she was told that in all probability it was due to "wind," and the matter was allowed to drop. Post mortem the brain and abdominal organs were found to be free from disease, but on opening the thorax the cause of death was soon discovered. The left pleural cavity was full of pus, and the lung was represented by a small hard mass situated at the posterior part of the chest, which seemed to me never to have expanded at all. The amount of pus present was about eight ounces. It is a very interesting question as to whether the disease was present before birth or was a subsequent development.

Sister's-avenue, Clapham-common.

A CASE OF SPERMATOCELE.

BY T. W. CARMALT JONES, F.R.C.S. EDIN.,

SURGEON TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

ON Dec. 14th, 1894, a man consulted me about a swelling connected with his left testicle. He was twenty-four years of age, and the swelling was first noticed when he was thirteen or fourteen. There was a feeling of weight and some pain, especially at night, and in bed the feeling of weight worried him. He had worn a truss for double inguinal hernia since the age of seven constantly. The swelling did not interfere with cycling, rowing, or wrestling, but he always wore a suspender. He had not gone in for gymnastics. There was no history of a blow, though he used to play football. On examination there was a tense sausage-shaped swelling, apparently in the left cord, projecting for about an inch above the testicle, with a smooth rounded upper end; lower down the swelling became indistinct at the back of the testicle, but below and behind there was again a smooth round-ended swelling projecting below and behind the testicle. No sense of fluctuation could be made out as the tumours were so tense; but on percussion the impulse was distinctly conveyed from one end to the other. The scrotal skin was very thick, and I could not see any light through the tumour. I diagnosed either an old hydrocele or a hæmatocele, and advised tapping. On Dec. 16th I drew off two ounces and a half of opaque, milky-looking fluid with a yellow tinge; it looked exactly like egg and milk, but on standing the yellow colour disappeared and the fluid became slightly brown. After the tapping the whole swelling disappeared alike above, behind, and below the testicle. The

gradually decreased, and the patient made an uninterrupted recovery. She was kept in bed for three weeks. For the first few days there was slight pain on swallowing. Peculiar constant whistling noises were heard for four weeks in the right ear. On Jan. 15th, 1895, the vision was $\frac{1}{2}$. There was very slight swelling of the upper lid, and no exophthalmos. The movements of the eye were normal, except for some slight difficulty in turning the eye outwards. The retinal veins were still much swollen and rather dark. The disc was normal.

This is undoubtedly a case of so-called pulsating exophthalmos, and caused by anastomosis of the internal carotid and the cavernous sinus. These cases, of non-traumatic origin, are more common in women and between the ages of thirty-five and forty-five. There are several rather interesting points in this case to which I will briefly refer. 1. There was no history of a blow or fall, no confinement or serious illness, and no arterio-sclerosis or heart disease. 2. There was intense pain for seven days before the noise was heard or the eye began to protrude. The pain was evidently caused by an aneurysm of the internal carotid, which increased in size for seven days and then broke

fluid was sent to Mr. Wyatt Wingrave for examination, and his report was as follows: "Report upon a specimen of fluid received from Mr. Carmalt Jones, Dec. 18th, 1894.—Quantity: two ounces and a half. Colour: café-au-lait, opaque. Reaction: alkaline. Specific gravity, 1032. Odour: faint; stale fish. Microscopic: (1) spermatozoa (dead), about 5000 in 1 c.mm.; (2) large nucleated round cells undergoing fatty degeneration; (3) fatty spheres about 3μ to 15μ in diameter; (4) granular pigmented spheres 10μ to 40μ in diameter; (5) small irregular granular masses 2μ to 5μ in diameter. Organic matter: fat in abundance, hæmaturia, serum albumen, and nucleo-albumen. Inorganic: chiefly phosphates and chlorides. Coagulation could not be induced except by heating. There were no crystals of either cholesterolin, spermin, or hæmaturia. On extraction with ether some free cholesterolin crystals were obtained. The fluid is evidently derived from a cyst connected with the testicle which has formed some association with the blood. Judging from the presence of pigment, it has been gradual in formation." The last time I saw the patient was on Jan. 16th, 1895. I could find no signs of refilling in the cyst; there was a great deal of thickening about the cord and testicle; he had had no pain, the sense of weight had entirely disappeared, and he had not worn a suspender for more than a week.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF STRANGULATION OF THE VERMIFORM APPENDIX IN AN INFANT SIX WEEKS OLD; REMOVAL OF THE VERMIFORM APPENDIX, WHICH WAS SUPPURATING; RECOVERY; REMARKS.

(Under the care of Mr. BILTON POLLARD.)

HERNIA of the appendix vermiformis has been observed both in the inguinal and femoral varieties of hernia—reducible, incarcerated and irreducible, and strangulated. Brieger¹ collected 41 cases of this form of hernia; 20 were inguinal, 15 femoral, and as regarded 6 the variety was not stated. In 6 the appendix was normal. Operation was performed in 28 cases, 16 being cured, 2 cured with fecal fistula following, and 5 died; in 3 the result was unknown. In the earlier cases the result of operation was not so favourable as in the more recent, probably because the condition is now better known, although sometimes very hard to diagnose, and the appropriate treatment adopted. Drs. Bull and Coley² give 6 additional cases in children—2 strangulated, 3 irreducible, and 1 reducible; 1 strangulated and 1 irreducible case died, the patient in the former case being only eight weeks old and almost moribund at the time of operation. The symptoms in strangulation of the appendix vary somewhat extensively, both as regards duration and severity. In a case of strangulation in a femoral sac described by Bayer³ they had commenced eighteen days before admission, and were chiefly local swelling and radiating pain; in another case there was constipation with some degree of prostration, but no vomiting. These are what may be called the dangerous cases, as on account of the absence of urgent symptoms the patients or their friends refuse operation until local or general peritonitis or perforation of the appendix has ensued. The length of the appendix varies from one inch to nine inches and a half, and it is not surprising that it is not sometimes found in the sac of a hernia in children, for its development in them is occasionally unexpectedly out of proportion to that of the adult, whilst its mobility may allow it to slip about. For the notes of this case we are indebted to Mr. Douglas Drew, surgical registrar.

A male infant aged six weeks was admitted on Jan. 22nd

on account of an inflamed, irreducible swelling which occupied the right groin and the right side of the scrotum. The latter had been enlarged since birth. The mother first noticed it when the child was fourteen days old. She pushed the lump up and it disappeared at once. On Jan. 19th the lump appeared again. It was larger than before, and the child became very restless. On the 20th the mother gave it a dose of castor oil, which acted freely the same day. It vomited after the castor oil, the swelling became much larger and harder, and the skin became red. In the evening of the same day the child was brought to the hospital and hot fomentations were applied. On the following day an attempt was made to reduce the swelling under chloroform. Something was felt to go back, but there was no slip or gurgle, and the swelling was not visibly reduced in size. The child vomited once during the day, and the bowels acted twice. Next day (the 22nd) it was, as stated above, admitted. The skin of the right side of the scrotum was red and œdematous. The right inguinal canal and the right side of the scrotum were occupied by a hard and very tender swelling, which was irreducible. Mr. Pollard operated. The tissues were thickened and inflamed. The tunica vaginalis contained a little fluid, and both it and the testicle were inflamed. The vermiform appendix occupied the funicular portion of the sac. It was red, and its middle third was considerably enlarged. A ligature was applied on the proximal side of the swelling. A circular incision was then made round the upper part of the appendix. Only the serous and muscular coats were divided. These were then retracted from the central mucous tube, and the latter was tied with a fine silk ligature at the highest point exposed. The mucous membrane was then divided below the ligature and the appendix was removed. The serous and muscular coats, being released, projected well beyond the ligature. They were inverted by three Lembert's sutures, which were tied over the end of the stump. A second series of Lembert's sutures were inserted, and as they were tied the central tube of mucous membrane was displaced upwards into the cæcum. The stump of the vermiform appendix was reduced into the abdomen, the neck of the hernial sac was ligatured and divided, and the operation was completed in the usual manner, the wound being entirely closed. The child's temperature rose after the operation to 101.6°F. It fell to normal on the following day and continued so afterwards. The wound healed by first intention and the child was discharged on the eighteenth day after the operation. The parts removed at the operation consisted of one inch and a half of the vermiform appendix. At a distance of half an inch from its tip there was an oval fluctuating swelling measuring half an inch in length and containing pus, which lay altogether external to the mucous membrane. The latter was thinned by ulceration opposite the abscess.

Remarks by Mr. POLLARD.—Strangulation of the vermiform appendix is rarely observed. In December, 1890, when operating for the radical cure of a right inguinal hernia, I found the vermiform appendix adherent to the back of the sac and was obliged to excise it preparatorily to ligaturing the neck of the sac. In this case there were severe local signs of strangulated hernia, but the absence of intestinal obstruction seemed to negative the idea that the hernial swelling was composed of intestine. I have met with two cases of strangulated hernia of the ovary which were diagnosed by the local signs of severe strangulation being unaccompanied by intestinal obstruction. Such a diagnosis was in this case out of the question owing to the sex of the child. Strangulation of omentum was a possible explanation of the appearances, but the rapid development and the severity of the local signs of strangulation were opposed to that view. The true explanation was only discovered at the operation. The method of removing the appendix which was employed in this case and in the earlier one already referred to appears to be worthy of remark. The appendix is sometimes simply ligatured and excised—indeed, the possibility of inverting the stump of the appendix and closing it with Lembert's sutures has been denied. It is, I believe, almost impossible to invert the mucous coat, but the serous and muscular coats are very movable and can be readily turned in over the central mucous tube, which is simply displaced upwards as the sutures are tied. By performing a sort of circular amputation and dividing the mucous coat at a higher level than the sero-muscular, as was done in these cases, the inversion of the latter layer and the apposition of serous membrane to serous membrane are

¹ Sajous' *Annual of the Universal Medical Sciences*, 1894, vol. iii., p. 23.

² *Ibid.*

³ *Centralblatt für Chirurgie*, 1876, p. 689.

facilitated. The abscess which was found between the coats of the appendix was apparently dependent on the strangulation and the taxis to which it had been subjected, for the canal of the appendix contained neither pus nor a concretion.

GENERAL HOSPITAL, NOTTINGHAM.

A CASE OF TUMOUR OF THE CORPORA QUADRIGEMINA; NECROPSY; REMARKS.

(Under the care of Dr. W. B. RANSOM.)

THE published cases of tumour of the corpora quadrigemina in which careful and accurate observation has been made are far from numerous, and this case is important, not only from the point of view of diagnosis of such growths, but also from that of treatment. Of course, from the surgical treatment nothing more was expected than a possible relief of some of the pressure symptoms by draining off cerebro-spinal fluid; but although the attempt was only partially successful it would appear to be fully justified by what occurred in a case described by Nothnagel.¹ In that case there were symptoms of tumour of the quadrigeminal bodies after a fall on the head, and after death a small glioma the size of a hazel-nut was found partly on and partly in the corpora quadrigemina; the ventricles of the brain were much distended. For some time before death cerebro-spinal fluid frequently escaped from the nose, a large quantity being often collected. When the flow was interrupted signs of cerebral compression occurred, stronger nystagmus, increase of reflexes, slower pulse, and involuntary escape of urine and faeces. After death, which occurred from coma, it was found that the escape of fluid had occurred through the perineural space of the olfactory nerves, which were atrophied. Sachs,² Thistle and Caven,³ Pawinski,⁴ Tissier,⁵ and Guthrie and Turner⁶ have described tumours of this region in recent years.

A youth aged nineteen years was admitted into the General Hospital, Nottingham, on Jan. 27th, 1894, on account of headache and strabismus. The patient dated his illness from an attack of "influenza" in the second week in December, 1893. After Christmas he resumed work for a week, but had then to stop because of pain in the head and the small of the back. About this time he noticed the strabismus, for which he consulted an ophthalmic surgeon. The head pain had gradually increased; it affected chiefly the temples and forehead, but had occasionally shot to the occipital region. There had been also some gnawing pain in the eyes, especially the left, and the sight of that eye had deteriorated. During the last week he had frequently vomited. There was no history of syphilis. On Jan. 28th the patient's mental condition and speech seemed normal, but he said his memory was not quite what it had been. He was pale and thin, but rather puffy about the eyes. There was slight drooping of both upper lids, more on the left, but both could be raised. There was a constant slight clonic movement of the upper lids, and with each lowering of the lids the eyeballs jerked inwards. The left eye deviated strongly inwards, and when he was told to look to the left this inward deviation was increased. The right deviated inwards to a less extent, and could be moved outwards nearly to the middle line. He could look downwards, but when he tried to look up the eyes turned inwards and very slightly upwards. The pupils were of medium size, the right slightly the larger. Both reacted sluggishly to light and accommodation. There was no facial paralysis. The muscles of the mouth and cheek moved normally; he could shut the eyes tightly and could wrinkle the forehead. The tongue did not deviate and was not wasted. The patient walked fairly well, though the feet were kept wide apart. There was no tendency to fall in any particular direction. Romberg's symptom was absent. The upper limbs presented no paresis, incoördination, or tremor. The knee-jerks and ankle-clonus were not obtained. The plantar, cremasteric, and abdominal reflexes were present, but not exaggerated. The patient complained of severe cutting pain in the forehead and temples, preventing sleep, and of some pain at the nape of the neck. There was some general cranial tenderness, most marked over the eyes. Smell, hearing, and taste were normal. Vision was very

defective. The patient could just read large print with the right eye, but with the left could not do this or count fingers. With the left eye he only just saw an object intercepting the light. Ophthalmoscopic examination showed a considerable pink effusion mottled with white spots over each optic disc. There was no other retinal change. There was no alteration in general sensation on the head, trunk, or limbs. In especial there was no sign of disease of the fifth nerve. He vomited frequently, usually after, but sometimes apart from, food. There was slight nausea. The abdomen was normal. The heart, lungs, generative organs, skin, muscles, and osseous system showed no sign of disease. The specific gravity of the urine was 1014; it contained no albumen or sugar, and no excess of phosphates. On Feb. 4th the headache continued to be intense. The gait was more staggering, the feet were kept wide apart, and the patient tended to fall to the right. There was slight weakness of the muscles of the left angle of the mouth. The clonic spasm of the eyelids and eyes had ceased. On the night of Feb. 9th the patient had a peculiar attack. He suddenly called out that his head was bad, and the nurse then found him with retracted head, very pale, and unable to speak, though he pointed to his throat. He did not seem to have lost consciousness, and there was no spasm of the arms or legs. The attack passed away in ten minutes, but he was very depressed and in great pain for some hours after it. During the last few days the patient had been much more dizzy when up, and could with difficulty walk alone, always tending to fall and to revolve to the right. On Feb. 10th the range of movement of the eyes was diminishing. The knee-jerks were still absent. On Feb. 13th the patient could not walk without support. For the last few days the vision had been gradually failing, so that now with either eye he could not do more than tell when a hand was held between him and the light. The pupils were of medium size, though once or twice they had been rather large, and reacted to light. The headache continued with great severity, and, although the patient's intellect seemed fairly clear, he was becoming very cross and sulky. The temperature since admission had been normal. The pulse had varied from 70 to 90. On Feb. 14th, as a result of a consultation, Mr. Joseph Thompson trephined over the left lobe of the cerebellum with a view of relieving intra-cranial pressure. When the dura mater was incised the cerebellum bulged prominently through the opening. A small drainage-tube was inserted. During Feb. 15th, 16th, and 17th there had been a very copious flow of cerebro-spinal fluid from the trephine hole. The patient had been free from pain, and for the first twenty-four hours after the operation seemed better, but afterwards he gradually became drowsy, then passed into a gradually deepening coma, and died on the afternoon of the 17th. The temperature rose to 103° F. on this day.

Necropsy.—On exposing the trephine wound a hernia cerebelli was found, the bulging portion of the cerebellum being inflamed and soft. On further examination a recent slight meningitis was found spreading from this point to the base of the brain. The rest of the cerebellum was normal. The convexity of the cerebral hemispheres showed no change beyond some engorgement of veins. On making horizontal sections of the hemispheres a patch of soft substance dotted with hæmorrhages was found in the roof of the hinder part of the left lateral ventricle, extending slightly to its outer side and inferiorly continuous with a mass of white growth in the posterior half of the left optic thalamus. The posterior corpora quadrigemina were enlarged, the left more than the right, and consisted of a similar white growth dotted with red which was continuous with that in the thalamus. The anterior corpora quadrigemina were small and almost obliterated. The pons itself was normal. The pineal gland was normal. There was no growth at the base of the skull. Microscopical examination of the growth in the corpora quadrigemina showed it to be a large oval-celled sarcoma.

Remarks by Dr. RANSOM.—In this case we have besides the ordinary signs of cerebral tumour—headache, vomiting, and optic neuritis—the further features of ophthalmoplegia and an unsteady, reeling gait—i.e., the two signs laid down by Nothnagel as pathognomonic of tumour of the corpora quadrigemina. The case differs from some in the fact that the ophthalmoplegia was well developed long before marked ataxy set in. In the earlier stage the diagnosis between growth from the base of the skull, of the corpora quadrigemina or pineal gland, and of the cerebellum was not certain. The loss of knee-jerks and paralysis of the sixth nerves might be explained by the hypothesis of cerebellar

⁵ THE LANCET, Feb. 2nd, 1895.

tumour pressing on the pons; while the paralysis of separate branches of the third and of the fourth nerve was compatible with a lesion involving them as they pass through the dura mater. Neither of these views, however, accounted for the clonic spasm of the upper lid and internal rectus, while it was not likely that a growth of the base of the skull large enough to cause such intense general symptoms would leave the internal and inferior recti and the nerves to the pupils intact. When the ataxy, barely observable at first, became fully developed the diagnosis of disease of the corpora quadrigemina became more probable. The marked interference with vision in this case is unusual, as in most cases such loss has been slight or very late in appearing. It cannot in this case have been due to implication of the optic thalamus or optic radiations, for it involved firstly and chiefly the left eye. There was never any hemianopia. It is possible that the optic neuritis may have caused it; but, on the other hand, one frequently sees a similar amount of effusion with little or no loss of visual power. The escape of the cells and fibres controlling the pupils and the slight affection of the internal recti are points of interest in connexion with the statements of Hensen and Vöckers as to the arrangement of centres on the floor of the aqueduct of Sylvius. These, the most anterior of the separate centres into which the nuclei of the third nerve are divisible, naturally escape injury from a lesion of the posterior corpora quadrigemina, while the centres for the upper lid, superior rectus, and external rectus are damaged. The paresis of the oral fibres of the left facial nerve and not of those to the orbicularis oculi is remarkable, considering the extent to which the third nucleus was injured. Mendel's view of the origin of the orbicular fibres of the seventh from the nucleus of the third would lead one to expect that these would suffer before the fibres to the mouth.

GENERAL HOSPITAL, SINGAPORE.

STRANGULATED DIAPHRAGMATIC HERNIA; NECROPSY;
REMARKS.

(Under the care of Mr. A. J. McClosky.)

PATIENTS who are suffering from a diaphragmatic or phrenic hernia do not often reach adult age; the large majority of congenital hernias of the kind described were found when necropsies were being made on children. The various ways in which they form are as follows: (1) as a consequence of weakening of the diaphragm in some part, permitting of the protrusion of some of the abdominal contents into the chest; (2) protrusion through a congenital opening in the diaphragm; (3) through one of the natural apertures; and (4) through an opening which has formed as the immediate or remote result of a wound or laceration of muscle. The protrusion is usually on the left side of the body, the presence of the liver being sufficient as a rule to protect the right side. We have, however, published in *THE LANCET*¹ a case of hernia on the right side, and mentioned others by Dr. Cornell, Dr. Hillier, and Dr. Murchison. The signs presented on the side of the chest into which the hernia has escaped are much like those of pneumothorax and may be mistaken for it; sometimes there is dullness on percussion in consequence of effusion or the presence of some of the solid viscera.

A woman aged twenty-two years was brought to the hospital on July 27th, 1894, complaining of vomiting, inability to swallow even liquids, and pain in the left side of the chest and back. The duration of her illness was only two days. She was the mother of two children, the last one being born six years ago. Her bowels were constipated. She had complete oesophageal obstruction, not being able to swallow even liquids. Liquids simply passed down the oesophagus for a certain distance and then welled up without any effort on the part of the patient. She was a well-nourished subject, and had always enjoyed good health. There was no history of injury, and the patient could assign no cause for her illness. She bore an anxious countenance, as of impending death; her body was cold and clammy, and the pulse rapid, small, and thready. The patient was in such a desperate condition—"doubled up," restless, and tossing about on the cot—that a thorough physical examination was almost impossible. She rapidly sank and died six hours after admission into hospital. At the necropsy a diaphragmatic hernia was discovered

at the most common site for such hernia—viz., on the left side. The herniated organs consisted of the stomach, the first part of the duodenum, omentum, spleen, and a few coils of the small intestine. The orifice was situated on the left side of the diaphragm close to its lateral posterior attachments to the ligamenta arcuata; it was circular in shape, smooth-edged, and of such a size as to admit the passage of five fingers. The stomach was "doubled up" upon itself, the greater curvature being uppermost in the left pleural cavity, and looking externally; while that portion of the stomach immediately adjacent to the cardiac end, between the oesophageal opening and hernial orifice, could be seen, tense and shining like a bladder, protruding on the abdominal side of the diaphragm. The pylorus with the first part of the duodenum was low down close to the orifice; the lesser curvature was directed inwards. The spleen lay behind and external to the stomach, against the pleural surface of the diaphragm, while immediately within the orifice were a few coils of the small intestine. The stomach was considerably dilated and presented numerous hæmorrhagic spots on its peritoneal surface; it contained a large quantity of dark-red bloody fluid, with partially digested food substance and shreds of mucus. The mucous membrane was acutely congested and eroded at parts, but not gangrenous. The heart was displaced considerably to the right, not extending to the left beyond the left lateral border of the sternum. The left lung was totally collapsed and pushed upwards against the clavicle, occupying only the supra- and infra-clavicular regions. The bowels were practically empty, the lumen contracted, and the walls atrophied; the mucous membrane presented a normal appearance.

Remarks by Mr. McClosky.—I am of opinion that the orifice in the diaphragm was a congenital malformation because of its situation, its smooth and even margin, its circular shape, absence of any adhesions, and absence of any history of injury or signs of any fracture of ribs.

CLINICAL SOCIETY OF LONDON.

Abdominal Section for Intestinal Obstruction caused by Volvulus of the Sigmoid Flexure.—Early Eriasion in Inflammation of the Sacro-iliac Joint.—Orchotomy for Enlargement of Prostate.—Large Intra-thoracic Cystic Goitre causing Dyspnoea and treated by Operation.

AN ordinary meeting of this society was held on April 26th, Mr. LANGTON, Acting President, being in the chair.

Dr. LUCAS BENHAM and Mr. SILCOCK related a case of Acute Intestinal Obstruction due to Volvulus of the Sigmoid Flexure. The patient was a female aged fifty-six years who had been affected with chronic mania and partial dementia for more than twenty years as the result of sunstroke in India some time before. She suffered from habitual constipation, which required the administration of simple aperients. She was thin, spare, and somewhat cachectic looking, but usually in fair health. The illness commenced with constipation, which was not relieved by the usual aperients. Sickness followed and became frequent and violent, the vomited matter containing some "coffee-grounds" material, but was not stercoraceous. She was first seen two days after the earliest symptoms appeared, and by that time the abdomen was greatly distended, vomiting occurring after every attempt to swallow. No obstruction could be felt per rectum, and no relief could be obtained by copious enemata &c. On the following day, therefore, the abdomen was opened, under chloroform, and the whole of the colon was found enormously distended, the seat of obstruction being, as was anticipated, in the sigmoid flexure, where the intestine was twisted a half-turn on itself, forming a volvulus. This was reduced. There was no peritonitis. The wound was closed and dressed antiseptically. There was immediate and great relief from the operation. No sickness or distension of the abdomen followed. A large quantity of fæces came away naturally. Slight pyrexia ensued, which lasted for ten days, but there was little other constitutional disturbance except a very dry brown tongue, which Dr. Benham was disposed to ascribe to the iodoform with which the wound was dressed. The last stitches were removed ten days after the operation, and the wound had completely healed a few days later. In a month from the date of the operation the patient was up and

¹ *THE LANCET*, May 16th, 1891: case described by Dr. W. A. Hollis.

about, looking as well as usual. This case was deemed worthy of record, as so few similar successful ones had been as yet reported—viz., only nine in all, and of these only one had occurred in this country. Besides these complete successes a few had also been recorded in which volvulus had been either temporarily or partially relieved by abdominal section.—Mr. PRABCE GOULD said that this subject had been introduced at a previous meeting by Dr. Herringham and Mr. Bruce Clarke. At that meeting he described one case and since then he had met with a second. The patient was a man aged forty years and of weak intellect, who had at one time been in an asylum. The pulse was not rapid and the temperature was normal, but the abdomen was tense and tenesmus was considerable; there was a little sickness. Nothing could be felt through the abdominal wall or per rectum. There was a history of gradual loss of flesh and strength for twelve months. He made a small incision as for inguinal colotomy and found a distended sigmoid flexure lying vertically along the middle line. He opened again in the middle line, and as he could not return the sigmoid flexure he incised it and let out much gas and faecal matter. As the torsion of the gut seemed to be recurrent he fixed it to the abdominal wall. Next day he tried to close the fistula, as the bowels had acted normally, but there was still an escape of faeces.—Mr. GOLDING-BIRD said that the interest of the case lay in the fact that the volvulus did not return, as was usually the case. Could the readers of the paper suggest why this had not happened?—Dr. GLOVEY remarked on the fact that both the cases referred to had been of unsound mind. He had seen a third case of a similar kind in consultation, and that also was in an asylum.—Mr. LANGTON said that he dealt with a case of volvulus two years ago. The patient, a female, presented a history of intestinal obstruction of gradual onset. She was so ill when he operated that he made an artificial anus. She recovered from the operation, but died two years later from influenza. It was a valuable procedure in these cases to empty the distended gut by incision.—Mr. ARBUTHNOT LANE said he had dealt with a case of this sort which was under the care of Dr. Hale White and himself. The patient died a few days after the operation from perforation of a stercoral ulcer in the portion of the sigmoid flexure which had been distended. The proper treatment in these cases was undoubtedly to resect the whole sigmoid flexure and fasten the descending colon to the rectum.—Dr. BENHAM, in reply, said that the bowels were kept empty after the operation, and to this he attributed the absence of return of volvulus.—Mr. SILCOCK, in reply, mentioned the case of a man between sixty and seventy years of age who was under Mr. Norton's care at St. Mary's Hospital, and for whom he suggested the opening of the sigmoid flexure and the free evacuation of the intestinal contents. Three days after operation the abdominal wall became gangrenous, apparently from division of the epigastric artery, for there was no peritonitis. Recurrence in these cases was generally due to the fact that the bowels were not emptied.

Mr. GOLDING BIRD read a paper on Early Erosion in Inflammation of the Sacro-iliac Joint. He detailed cases in which in an early stage of tuberculous disease he had operated upon the sacro-iliac joint, and the method he advanced was an elaboration of one he had employed in a single case fifteen years ago. Its object was, by removal of the iliac surface of the joint, to permit of its thorough exploration and cleansing. The special points upon which he laid stress were as follows: the importance of early recognition of sacro-iliac inflammation (and he insisted upon the value of pain elicited by pressure over the root of the posterior inferior iliac spine); early operation, as in any other tuberculous joints; not to wait for local objective signs; and especially not to wait until disorganization had proceeded to the formation of sinuses. Sinuses were useless as routes to follow in operating, but deliberate removal of the ilium from the posterior inferior iliac spine upwards and forwards over the whole area of the joint was insisted upon. The after-treatment was very simple, and appeared from his cases to be short, an adult patient being able to walk about and bear his weight on the joint by the eighth week.—Mr. CROFT was glad that the theory of early interference in joint disease, of which he had so long been an advocate, had been brought to bear upon sacro-iliac disease, which used to be looked upon as hopeless to deal with surgically, and the patients affected with it were relegated to rest for an indefinite time. They thus often passed through several years of suffering and were unable to carry on their usual occupations.

It was occasionally difficult to establish a diagnosis. In several cases pressure upon the wings of the os innominatum was not sufficient to elicit pain except when the anterior superior spinous processes were pressed towards each other. He had often found it difficult to elicit pain by pressure directly over the region of the joint, and in this he differed from Mr. Golding-Bird. He had not given up splints in the treatment of these cases, but the principle seemed a sound one.—Mr. GOLDING-BIRD, in reply, said that he would adopt splints during the expectant treatment of these cases, but not after operation.

Mr. MANSELL MOULLIN read a paper on two cases in which Orchotomy was performed for Enlargement of the Prostate. The first case was that of a man seventy-four years of age under the care of Mr. Birch of Lower Clapton. The prostate was of enormous size, the urine ammoniacal, and the bladder so contracted from persistent cystitis that it could only hold two ounces of fluid. There was intense strangury; a portable urinal had to be worn constantly, and the patient had to rise fourteen or fifteen times every night, the longest spell of sleep being three-quarters of an hour, in spite of the frequent use of morphia suppositories. Ten days after the operation the patient had dispensed with morphia and could sleep sometimes for an hour and a half. The prostate, as felt per rectum, was decidedly smaller. The stream of urine was larger. The reaction was neutral, and small masses of phosphates were beginning to come away. One month later the urine was acid; masses of phosphates were still coming away, and more could be felt. The strangury had almost gone, and there was only a faint cloud of mucus. The bladder could hold four ounces of urine and was much less sensitive when a catheter was passed, and the general condition of the patient had improved immensely; instead of going rapidly downhill he was gaining ground. The second case was that of an enormously stout man under the care of Mr. Houchin of Stepney. The prostate was exceedingly large, the bladder capacious, and the urine at the time acid with only a little albumen, but there had been repeated attacks of cystitis and hæmaturia; the patient had to use a catheter every hour, day and night, and no urine had been passed spontaneously for upwards of fifteen months. The patient bore the operation well, and everything progressed favourably for a week; then he was seized with extreme dyspnoea, from which he rallied for a time, but the attack returned again and again, with hæmaturia and profuse diarrhoea, and death ensued on the eleventh day. On the two days before death bloodstained urine was passed spontaneously by the penis on several occasions. At the necropsy the heart was found to be soft and fatty, the kidneys (one especially) were cirrhotic, and all the abdominal thoracic organs were loaded with fat. The bladder contained calculus, which had been concealed behind the prostate, and some bloodstained urine. Its walls were deeply congested and ulcerated in places. The prostate, which was uniformly enlarged, was very soft and flabby, and the forefinger could be passed easily down the prostatic urethra. An outgrowth from the prostate that projected upwards into the bladder showed unmistakable signs in its consistence and shape, and in being covered over with wrinkled mucous membrane, of its having undergone a recent diminution in size. It was pointed out that although one of these cases proved fatal and in the other the success, though quite as great as could be expected from what was known beforehand of the condition of the bladder, was not nearly so great as that of Mr. Mansell Moullin's former case, of which an account was given at the last meeting of the British Medical Association, they both of them bore testimony to the fact that enlargement of the prostate, no matter how great it was, disappeared within a very short time after orchotomy had been performed. It was urged that sufficient evidence had been brought forward to justify the assurance being given to those who were suffering from the effects of this disease that if the operation were performed the enlargement would disappear, and unless it had been already hopelessly ruined by cystitis and catheterisation the bladder would recover its power. Mr. Mansell Moullin advocated the use of the word "orchotomy" in preference both to castration and to "orchectomy," which had been suggested in America as being the natural derivative from the Greek, *ὀρχοτομήν*, to castrate.—Mr. LANGTON said that years ago he operated on a man aged sixty-eight years who had an enlarged prostate and acute senile tuberculous disease of the testis on the right side. He performed castration on that side and noticed that this was followed by diminution in size of the corresponding side of the prostate. Later the left testis became also affected

with tuberculous disease, and it was also removed; the prostate then completely shrank. The patient was at present alive and in good health.—Mr. GOLDING-BIRD said that it was of immense importance to publish all cases of castration, in view of the correspondence which had recently taken place on this subject, and observations were required as to whether removal of one testis was followed by diminution of the prostate on the corresponding side. He objected to the term "orchotomy" and thought that if any departure from castration were required the term "orchectomy" might be used.—Mr. PEARCE GOULD said that the year before last he removed the right testis of a man for tuberculous disease; there was no appreciable shrinking of the prostate after that operation. During the present year the other testis had become tuberculous and was also removed. There was a great shrinking of the prostate after the second removal.—Mr. MANSELL MOULIN, in reply, said that he believed that though the removal of one testicle would have no effect on a prostate of normal size, yet an enlarged prostate would undergo unilateral shrinking.

Mr. BOWLBY related a case of large Intra-thoracic Cystic Goitre causing Dyspnoea which was treated by operation. The patient was a woman aged thirty-four years. She had noticed a small swelling in the episternal notch for about two years, and had suffered for the same time from slight shortness of breath. During the few months preceding her admission into St. Bartholomew's Hospital the difficulty of breathing had increased, and she had suffered from attacks of transient but severe dyspnoea. The attack from which she was suffering on admission had followed exposure to cold and wet and was accompanied by nasal catarrh and bronchitis. The swelling in the neck had also increased in size. The patient was found to be suffering from very severe dyspnoea with recession of the chest walls and cyanosis. Her respirations were rapid and her temperature 103° F. An examination of the neck showed very little external swelling to account for such serious symptoms. There was some fulness in the episternal notch, and the thyroid gland felt a little enlarged. When the patient coughed, however, the swelling increased in a most extraordinary manner, and a large rounded mass was suddenly extruded from the chest into the neck and as suddenly disappeared. The way in which the tumour was projected reminded one very much of a sudden protrusion of a large hernia during coughing. The tumour moved very slightly on deglutition. An examination of the chest revealed a large area of dulness behind the sternum and cartilages of the first three ribs and continuous with the area of cardiac dulness. There were loud mucous râles in the trachea and bronchi. The diagnosis was intra-thoracic goitre, and an operation was performed as soon as possible. An incision in the middle line showed that the growth was cystic and attached to the left lobe of the thyroid. The trachea was next opened on account of the cessation of respiration, and the cyst was incised. It contained more than a pint of clear fluid, and when emptied was found to have compressed the trachea backwards and thrust itself between the apices of the lungs. Its walls were very thin and reflected over the large vessels, so that on looking into the cyst the aorta, the innominate, and the carotid vessels were easily distinguished, as was also the base of the heart, on which the cyst rested. The thyroid gland was otherwise not enlarged or diseased, but had been displaced a little by the tumour. The patient made a rapid recovery, and the wound healed in three weeks. When last seen, after an interval of several months, there was no re-collection of the fluid in the cyst.—Mr. GOLDING-BIRD asked why comparatively small unilateral enlargements of the thyroid gland were so frequently accompanied by dyspnoea. He believed that this symptom in many cases was functional. On one occasion, after opening a substernal abscess, he had felt the arch of the aorta.—Mr. BOWLBY, in reply, said that in the case related the cyst had become impacted behind the sternum, and therefore the dyspnoea had an obvious cause.

scientific interest, and of no less practical importance because the antitoxin treatment of diphtheria, probably the first step towards an entirely new field of therapeutics, was the direct outcome of the close study of its phenomena. The first fact to be taken into consideration was that pathogenic bacteria produced their effects on the organism by means of poisons or "toxines" which they elaborated in the fluids of the body, as was well seen in the production of all the symptoms of diphtheria or of tetanus by the inoculation of sterilised culture fluids, without a trace of the bacilli themselves. These toxins were intensely virulent, but others, as that of the pneumococcus, were extremely feeble. The bacilli of diphtheria and tetanus when inoculated did not invade the vascular system, but multiplied in and around the seat of inoculation only, though the toxins they produced were diffused throughout the body. These might be taken as types of toxic diseases; though in the case of tetanus the inoculation of washed spores into a healthy wound produced no effect unless the tissues were lacerated or suppurating, or other bacteria were introduced at the same time and place. In septic diseases, on the other hand, the toxins were feeble, but the bacteria invaded every tissue and fluid of the organism. This was well seen in the study of the coccus of pneumonia in the rabbit. Some, as septicæmic, partook of the character of both, and some acted in one way or the other under different circumstances. We must consider the power of the body to destroy the bacteria or inhibit their growth, and the power of resisting the effects of their toxins, the former factor being most important in the case of the septic and the latter in that of the toxic diseases. Immunity might depend on either condition or on both. It was either natural or artificial and acquired. Fowls, pigs, and white rats were immune to anthrax; birds generally to the pneumococcus; mice to the toxine of diphtheria; and fowls to that of tetanus, just as they were to large doses of morphine. They would, however, succumb to anthrax if depressed by cold and ill fed. An artificial immunity might be acquired in several ways, as by inoculation with a mild or artificially attenuated virus, or by minute doses of a virulent one, or by non-fatal doses of the pure toxine. Anthrax virus could be attenuated by cultivation at a high temperature or by the addition of certain antiseptics. As a rule, immunity obtained by means of the toxins was less permanent than that from inoculation of living microbes. Time was required to establish immunity by means of toxins and such immunity did not last long, both periods being longer the greater the effect of the inoculation. It was easier to render an animal immune to fatal doses of the living bacteria than to those of the toxine; and when this latter immunity was obtained that to the bacteria was also, but the converse did not hold good. A fallacy of observation might, however, arise from the fact that living bacteria were often retained in the tissues long after apparent recovery and called into renewed activity by the injection of toxine, they and not it being the cause of the subsequent fatal attack. In some few cases a very transient immunity had been produced by the intra-peritoneal injection of dead bacteria &c. But of infinitely greater value was that conferred by injection of the serum of a highly immunised animal. The immunity was of far shorter duration than that produced by vaccination, but this method had a therapeutic as well as or even greater than its prophylactic, and unlike vaccinations was available after the disease had developed. This was the antitoxin treatment of diphtheria and tetanus. Turning to the properties of the cells and fluids of the body in their relation to bacteria, Dr. Washbourn referred to phagocytosis as the most seductive theory of immunity. To Metschnikoff, who had studied the process throughout the animal kingdom, we owed all our knowledge of the subject. The amoeba, as was well known, was capable of surrounding and digesting particles of food, including living bacteria. Among these Metschnikoff had observed a small unicellular micro-organism, the microsphaera, which, however, instead of being digested multiplied within the amoeba and ultimately destroyed it. Such a struggle between the invading microbes and the protoplasmic cells of the body occurred, according to Metschnikoff, in every case of infection, ending in recovery or in death as the cells or the microbes were victorious. The struggle and the alternative results were well seen in the Daphnia, a small freshwater crustacean, and the parasitic Monopora, which entered the tissues from the alimentary canal, and in a large number of the invertebrata phagocytes played an important part. Among vertebrata the phagocytes belonged mostly to the class of leucocytes, which Metschnikoff divided into lymphocytes, eosinophiles, neutrophils, and

EPIDEMIOLOGICAL SOCIETY OF LONDON.

Immunity.

A MEETING of this society was held on April 19th, Mr. SHIRLEY F. MURPHY, President, being in the chair.

Dr. J. W. WASHBOURN read a paper on Immunity, which was, he pointed out, a problem of the deepest

mononuclear leucocytes. Of these, the two latter, together with the endothelial cells of the lymphatics and kidneys, were phagocytic, even when removed from the body, and that they were capable of thus devouring bacteria in the living animal was easily proved by experiments such as the introduction of anthrax bacilli under the skin of a pigeon or of those of tubercle into the blood of a rabbit, when they would be found to be taken up by the leucocytes and by the endothelium respectively, and successful cultures from such leucocytes showed that the bacteria might resist digestion for some time. The migration of leucocytes through the walls of the vessels in inflammation around the seat of an inoculation was due to a power possessed by various substances of attracting or of repelling amoeboid cells, and known as positive and negative chemotaxis. It could be studied in certain protozoa, as the myxomycetes, and in the vertebrata by inserting under the skin capillary tubes open at one end and containing chemical substances. On removing the tubes after some days the contents, if positively chemotactic, will be filled with leucocytes. That the blood and lymph serum had bactericidal powers was first observed by Nuttall, and carefully investigated by Buchner, Behring, and others. If serum were inoculated with a cultivation, and the number of bacteria present estimated day after day by plate cultures, it was found that they gradually fell off until they disappeared altogether, or after having sunk in number for a time began to increase until they were more numerous than at first. It had been suggested that the serum contained a bactericidal substance called "alexine," and that the bacteria secreted an antagonistic "lysine"; both were hypothetical, but the fact remained that bacteria, if numerous, could resist the undoubtedly bactericidal action of the blood, which was also very easily destroyed by physical agencies such as the exposure of the serum to a temperature of 60°C. The bactericidal property was most conspicuous in inflammatory exudations and was doubtless due to some substance secreted by the leucocytes, among which Hankin first indicated the eosinophile cells as the most active. But the serum was not merely bactericidal; it could be made antitoxic. Behring and Kitasato were the first to show that the serum of animals immunised by inoculation to the poison of diphtheria or tetanus possessed the power when inoculated into others infected with the respective diseases of neutralising the poison and cutting short the morbid process; and the more frequently the immunised animal was injected with the toxine the more powerfully antitoxic its blood became. Ehrlich had shown that two vegetable poisons, ricine and librine, acted in a strictly analogous manner. Serums were thus antibacterial or antitoxic, the latter being antibacterial also. The bactericidal property of a serum was very easily destroyed by heat, but the antitoxic or protective property was not, and the substance in which it resided could not be precipitated without losing its efficacy. It was scarcely necessary to state that all antitoxins were specific or efficient against no toxine but that of the disease whence they were derived. Such were the factors in immunity—viz., phagocytosis, bactericidal substances and protective serums, the last of these being outside of the question of natural immunity. Yet the problem of natural immunity was a complex one, special factors coming in; thus the low temperature of the frog's blood enabled it to resist inoculation with tubercle bacilli, and fowls were unaffected by tetanine as they were by morphine. The blood serum of white rats destroyed anthrax bacilli even out of the body, but their resistance to the action of the pneumococcus could not thus be explained. All such cases Metschnikoff would refer to phagocytosis, but marked phagocytosis might occur and death yet follow; indeed, in the case of rabbits infected with anthrax the bacilli had been seen to escape from the interior of the phagocytes and multiply in the fluids. Again, in the exudation around the seat of inoculations many of the leucocytes were not phagocytes and the exudation serum might be a powerful bactericide. Both agencies were involved in the resistance offered to infection and phagocytosis, very rarely alone. The problem of acquired immunity was further complicated by the introduction of a new and artificial factor—the protective power of the serum. An antitoxin, as that of diphtheria or tetanus, neutralised the paralyzing action of the toxine on the cells, allowing phagocytosis to have full play; for the serum of immunised animals had no bactericidal properties, and the spores of tetanus, if washed free from any trace of toxine and introduced into the body of a susceptible animal, were speedily ingested and destroyed by

the phagocytes. Immunity acquired towards the septic diseases was even more obscure and complex, so that, pending the results of experiments which might throw light on the subject, it was better to refrain from conjecture.

HARVEIAN SOCIETY OF LONDON.

Syncopeal Bradycardia.

A MEETING of this society was held on April 18th, Dr. WILLIAM HILL, Vice-President, being in the chair.

Dr. ALEXANDER MORISON read a paper on Syncopeal Bradycardia. After referring to the literature of the subject he treated it under the following heads: 1. Endocardial bradycardia, in which the chief factor was increased endocardial blood pressure. This bradycardia of overstrain, occurring at all ages, was illustrated by cases. 2. Myocardial bradycardia, due to fatty or fibrotic degeneration of the myocardium, or to changes assumed to exist in the intrinsic neural mechanism of the heart. Cases illustrating this condition in its presyncopeal and syncopeal phases were given, and sphygmograms taken from a case under Dr. Morison's observation were shown. 3. Exocardial bradycardia or that due (a) to reflex and transient nerve irritation, especially in the pneumogastric territory; (b) to poisons, such as digitalis, opium, and chloroform—well-marked pulsus bigeminus caused by digitalis in a case of double mitral disease was illustrated by sphygmograms; (c) to constitutional and extra-cardial diseases, such as rheumatism, syphilis, and meningitis. 4. Compound bradycardia or cases in which various factors played a part difficult to apportion ariht. 5. Doubtful cases, in which well-marked clinical bradycardia could not be ascertained after death to have rested upon a discoverable cause. The etiology of the subject was next considered, and Dr. Morison showed that bradycardia could not be associated exclusively with most anatomical changes, either in the heart or neighbouring organs, because such were much more frequently attended by cardiac acceleration. He ascribed a preponderant rôle to the influence of the cardiac nervous system, the power of which to modify the heart's action rhythmically and arrhythmically was illustrated by several sphygmograms. He laid especial emphasis on the important fact, noted by Dehio as well as by himself and others, that cardiac accelerants had little appreciable effect upon the heart in persistent bradycardia. He showed that this failure to accelerate applied to belladonna, trinitrin, and alcohol alike, as well as to such movements, locomotor or pyrexial, as under normal circumstances quicken the heart. Dr. Morison closed his remarks with references to the diagnosis, prognosis, and treatment of these cases, and quoted two instances, one recorded by Flint, which showed that persistent cardiac bradycardia might result in recovery, and another mentioned by Tripiet, in which iodide of potassium cured a persistent case due to syphilis.

Dr. William Hill, Mr. Peyton Beale, Dr. Cagney, and Dr. Basil Morison took part in the subsequent discussion, and Dr. Alexander Morison replied.

MIDLAND MEDICAL SOCIETY.

Intra-peritoneal Hemorrhage.—Exhibition of Cases and Specimens.

A MEETING of the above society was held on April 24th at the Birmingham Medical Institute, the President, Mr. T. F. CHAVASSE, being in the chair.

Dr. THOMAS NELSON showed a patient with a large Nævus between the thumb and forefinger, about the size of an orange, with a small division extending through between the metacarpal bones of the index and second fingers. It has been slowly growing for twelve years and does not cause any inconvenience.

Mr. F. MARSH showed a girl aged nineteen years whom he had Trephined on March 2nd, 1894, for Epilepsy which had developed after a fall on to the forehead ten years ago. There was a depressed scar about an inch above the left eyebrow. On removing a disc of bone beneath this a small perforation was found in the bone through which the dura mater had protruded and become adherent to the scalp tissues. This was severed and the bone was reimplanted. Primary union took place, and there had been no recurrence

of the fits, although thirteen months had elapsed since the operation.

Mr. F. MARSH also showed a boy aged thirteen years whom he had Trephined on Oct. 5th, 1894, for Headache and Vertigo on slight exertion. About nine years ago the boy fell and struck his forehead against a kerb-stone and had suffered much from headache since. The pain commenced at the site of a slightly depressed scar two inches above the right eyebrow and radiated over the head. A disc of bone was elevated at this spot, but no depression of the internal table was found. The dura mater was, however, adherent. The adhesions were separated and the bone was reimplanted. A rapid recovery was made, and there had not been any recurrence of the symptoms.

Mr. E. LUKE FREER showed a new Spinal Apparatus.

Mr. C. MARTIN showed a cheap and efficient Apparatus for the Sterilisation of Instruments.

Mr. JOHN W. TAYLOR read a paper on Intra-peritoneal Hemorrhage the result of Tubal Pregnancy. The paper dealt first with diffuse hæmorrhage from rupture of the tube, its features, recognition, and treatment, and secondly with localised intra-peritoneal hæmatocele, its causation, consequences, and varieties. The views of Professor Sönger of Leipzig and of the writer regarding "encapsulated" or "solitary" hæmatocele were discussed, and some critical remarks on the general subject of intra-peritoneal hæmatocele concluded the paper.

Reviews and Notices of Books.

Lehrbuch der Allgemeinen und Speciellen Pathologischen Anatomie für Aerzte und Studierende. Von Dr. ERNST ZIEGLER, Professor der Pathologie, Anatomie, und der Allgemeinen Pathologie an der Universität Freiburg. Achte, neu bearbeitete Auflage. Erster Band: Allgemeine Pathologie. Jena: Verlag von Gustav Fischer. 1895. (Text-book of General and Special Pathological Anatomy, for Practitioners and Students. By Dr. ERNST ZIEGLER, Professor of Pathological Anatomy and of General Pathology at the University of Freiburg. Eighth Edition. Vol. I. General Pathology. Jena: Gustav Fischer. 1895.)

THE welcome originally accorded to Professor Ziegler's "Lehrbuch" has been more than justified by the rapidity with which new editions have been called for. Indeed, it is no exaggeration to say that this work marked the opening of a new epoch in the study of pathology, and that it from the first set a high standard of excellence. Its merits were manifold, but above all others may be cited the clearness of literary description and the wealth of admirable illustrations which it displayed. It had succeeded to the favourite text-book of Professor Förster, but in originality and power it left that work far behind. Nevertheless, in these days of scientific progress no text-book can hope to retain a hold on the favour of the student which fails to keep abreast with the increasing knowledge of the times. The author, fully cognisant of this fact, has in each succeeding edition amended and added so much that practically the book has assumed a new form without in the least diminishing its popularity. The enormous strides with which bacteriology has advanced and the problems which surround it have not escaped his notice, and the result is that the first volume has grown considerably in dimensions and in value. Professor Ziegler has with this eighth edition made a new departure in giving it the wider title of "General Pathology," instead of that of "General Pathological Anatomy," which it formerly held. Forming now a bulky volume of upwards of 700 pages, and illustrated by 453 figures, some of which are coloured, and all of which are remarkable for their delicacy and fidelity, it constitutes the best compendium extant of the science. In his prefatory remarks the author justifies his extensive revision, rightly maintaining that the work of greatest utility is not that of a condensed manual, which can only give results and conclusions, but that in

which each topic is treated fully and with due explanation. He recognises that the aim of pathology is to give a clear insight into the processes of disease and to be of practical value at the bedside, and in the book before us he has certainly spared no pains to expound principles and describe the facts on which these are based. The introduction of a section devoted to the causes of disease and of chapters dealing with fever, immunity, and other general questions, has become a necessity, whilst the discussion of inflammation and the vital processes connected with it has been considerably expanded and modified. In the chapter on tumours we have one of the most complete and rational descriptions of the histological characters of these formations. Disorders of development and malformations are also most amply illustrated. But the crown of the work lies in the thoroughly systematised and accurate details of the parasitic affections which form so large a part of infective disease. The utility of the work is enhanced by the ample bibliography appended to each section, and to our thinking the book is one which is quite indispensable to the advanced student of pathology. This is the more evident since it may be truly said to occupy a unique position among text-books.

Elementary Practical Bacteriology, including Bacteriological Analysis and Chemistry. By A. A. KANTHACK, M.D., M.R.C.P., Lecturer on Pathology and Bacteriology, St. Bartholomew's Hospital; and J. H. DRYSDALE, M.B., M.R.C.P., Casualty Physician, St. Bartholomew's Hospital. London: Macmillan and Co. 1895.

THIS is one of the best of the practical handbooks for laboratory instruction that we have met with. Dealing with a difficult and complicated subject, it leads the beginner, by extremely well devised and clear instructions, through all the methods most in vogue, not merely for cultivating and staining micro-organisms, but also for observing the modifications in their life-history effected by temperature, amount of sunlight, the presence or absence of oxygen, and so on. In another section full directions are given for the examination of air, water, and food, as well as for testing the efficiency of filters. In the third section the student is taken through the methods employed for separating the toxines, albumoses, &c., which result from the chemical changes set up by the agency of the various organisms, such as the bacillus diphtheriæ and the ptomaines which result from the putrefaction of proteid matter. The methods employed throughout are described in clear and definite language, and the various steps are given in praiseworthy detail. Many practical handbooks are rendered useless by the directions being too condensed, the writer assuming that the reader is familiar with the details of laboratory work. This defect has been avoided by the authors, who have managed, nevertheless, to keep the book in small compass by omitting all padding. The book is written for those who are attending a course in a well-equipped laboratory, and for such it can hardly be improved upon; but there are many practitioners, both here and in the colonies, who have not had the advantage of laboratory instruction in their student days, but who have taken up the study of bacteriology, and we hope that in future editions the authors will see their way to increasing the usefulness of their work by a short introduction on apparatus, and an appendix on the best method of obtaining pure cultures of the various materials which they prescribe for use in the different lessons.

Directions for Laboratory Work in Bacteriology. By FREDERICK G. NOVY, Sc.D., M.D. Michigan: George Wahr. 1894.

THIS is essentially a laboratory handbook, and has been arranged so that it may be made to serve both as an instruction book and as a note-book, in which drawings and

such additional notes as may be desirable may be made. It is essential in such a book that the teaching should be didactic, and in some cases even dogmatic. The course for which this is a text-book is supposed to extend over twelve weeks, instruction being given daily; and certainly anyone who devotes this amount of time to the subject and carefully follows out the directions given will have acquired a knowledge of the technique and of the elementary facts of bacteriology that will place him in a position to continue the study of the subject and to carry on original investigation. The instructions are in many cases far from complete, but this arises presumably from the fact that the author intended the work simply to serve as a skeleton text-book, the gaps in which are to be filled up from time to time and as individual necessity arises. The book, therefore, in the hands of a student under a good teacher may prove invaluable, but it can scarcely be looked to for much help in clearing up the many difficulties that constantly arise in the laboratory. The lessons are progressive, but two subjects are usually carried on side by side; thus, to begin with, classification and life-history are considered side by side with the preparation of nutrient media and general bacteriological technique. Then follow descriptions of various typical micro-organisms, all of which are carefully drawn up, followed by the various methods in which their study is carried on. The latter part of the book is devoted to what is described as special work—i.e., preparation of tissues, cutting and staining of sections, and the preparation of these sections for the examination of various pathogenic micro-organisms. The testing of disinfectants is then taken up, and at the end is given a very complete list of apparatus and accessories. The work, as a whole, may be recommended as a good laboratory text-book, especially when supplemented by oral teaching.

Illustrated Lectures on Ambulance Work. By R. LAWTON ROBERTS. Fifth Edition. London: H. K. Lewis.

THAT this book has reached a fifth edition so few years after the date of its first appearance is good evidence of its popularity and of its meeting a want. It consists of a course of five lectures and an appendix. In the first lecture the aims of the St. John Ambulance Association are described, the necessity of universal instruction in "first aid" is urged, and a general description of the structure and functions of the human body is given. The uses of the triangular bandage and the application of first field dressings are also described. The second lecture treats of bleeding, the third lecture of broken bones, the fourth lecture deals with sudden attacks of illness, and the fifth lecture with the methods of lifting and carrying the sick and injured. The appendix contains much advantageous information and many useful instructions. The lectures strike us as being too long, and we think the book more suitable to lecturers than to those seeking instruction, who will, moreover, find all that is essential in Shepherd's "First Aid to the Injured"—the well-known little manual issued by the St. John Ambulance Association. The book is copiously illustrated; those illustrations which deal with hæmorrhage and the application of tourniquets are particularly good. Surely it was unnecessary to give a special illustration to depict the well-known "safety pin." In the preface to this addition useful statistics of the work of the St. John Ambulance Association are set forth, and reference is made to the appointments of Surgeon-Major Hutton as "Organising Commissioner" to the Association and of Colonel Thackeray, V.C., as Commissioner of the St. John Ambulance Brigade. The work done by another body, "The Invalid Transport Corps," is also brought into prominence. The fifth section contains fifteen pages on Military Ambulance Organisation, an able summary of a very interesting subject,

and one likely to do something towards "educating public opinion" to the needs so often pointed out by Brigade-Surgeon-Lieutenant-Colonel Evatt and other officers of the Army Medical Staff.

Outlines of Zoology. By E. J. ARTHUR THOMSON, M.A., F.R.S.E., Lecturer on Zoology in the School of Medicine, Edinburgh. Second edition, revised and enlarged, pp. 820, with 266 illustrations. Edinburgh and London: Young J. Pentland. 1892.

THE new edition of this excellent treatise, which is one of Young J. Pentland's students' manuals, has been considerably enlarged, for not only have 180 pages been added, but much space has been gained by relegating details to smaller type. The whole work has undergone systematic revision, facts recently observed being inserted and pains having been taken to make the meaning clearer where there was previously any obscurity. The first chapter, giving a general survey of the animal kingdom, has been rewritten, and the second chapter, on Comparative Physiology, has been added by Miss Marion Newbigin, B.Sc., who, the author states in his preface, has assisted him throughout in the preparation of this edition. A conscientious revision of each chapter appears to have been made, and many new paragraphs and sections have been introduced—such, for example, as those dealing with the development of clepsine, the development of the crustacea generally, and the disposition of the vertebral column in the fish, frog, lizard, and bird; the description of a lizard, of a snake, and so on—all of these being intercalated with the accounts given in the first edition. Many additional illustrations are given. Some improvement might still be made in this direction. For example, the statements made under the head of the nervous system in lizards, that "the brain consists of the usual parts," and under the same head in ophidia that "the brain presents no remarkable peculiarities," supply no information to the student. A good diagram showing the parts would be of much assistance.

In our notice of the work on a former occasion we drew attention to its excellence as a manual of instruction for those preparing for the higher examinations, and it may now be regarded as one of the most reliable at the disposal of the student.

Transactions of the Royal Academy of Medicine in Ireland. Vol. XII. Edited by WILLIAM THOMSON, M.A., F.R.C.S. Dublin: Fannin and Co.; London: Baillière, Tindall, and Cox.

THIS volume contains selected papers read before the various sections of the Royal Academy of Medicine in Ireland, many of them being of much interest. Appended to the text of each paper is a report of the discussion which ensued, a feature which adds to the value of the volume. Of the papers contributed to the Section of Medicine we note one on Pernicious Anæmia by Dr. James Craig, who gives an impartial summary of the growth of knowledge on this obscure subject. He points out that arsenic is not always beneficial, and thinks that the recommendation of Dr. Wm. Hunter to employ intestinal antiseptics is one which might be followed with advantage from what is known of the character of the disease. Mr. J. J. Burgess writes upon Malignant Endocarditis, the case upon which his paper is based being one of great obscurity in a pregnant woman. Abortion occurred during the illness, the course of which was marked by irregular pyrexia, marked nervous symptoms, and finally cerebral embolism. There is a remarkable record of a case of Associated Paralysis of the Portio Dura and Pneumogastric Nerves by Dr. J. W. Moore, apparently depending upon supuration in the sphenoidal sinus; the patient recovered. The subject of Graves' Disease and its points of contrast with Myxœdema are discussed by Dr. James Craig. There is

also a paper on Tetany by Dr. A. R. Parsons, besides others on Influenza, Cancrum Oris in Typhoid Fever, &c. In the Section of Surgery Mr. F. Alcock Nixon describes a case of Removal of a Tumour of the Brain, and details the several plans suggested for cranial topography by Professors Thane, Reid, and Fraser, the last being in his opinion the most reliable. Mr. T. Miles gives with much clearness the grounds for a resort to Laminectomy in Spinal Injuries, and Dr. Kendal Franks records a remarkable case of Fibrous Stricture of the Oesophagus treated by gastrotomy and dilatation from below according to Loreta's method. Mr. J. S. McArdle writes upon Nephrorrhaphy and Nephrectomy. He incidentally mentions that he is not inclined to concur in the opinion expressed by some that nephrectomy is of no use in renal sarcoma. The same surgeon contributes to the Section of Obstetrics a paper on the Operative Treatment of such Herniæ as appear the result of Congenital Defect of Linea Alba, or as the outcome of Laparotomy. In the Section of Pathology there is an exposition of the current doctrines on Immunity in a paper by Dr. J. A. Scott, and also a description of a case of Locomotor Ataxy with Charcot's Disease. A series of plates illustrative of points in the development and morphology of the central nervous system are explained by Dr. Alec Fraser; they formed part of a demonstration given at one of the meetings of the section, and constitute a distinct feature of an instructive and valuable volume.

LIBRARY TABLE.

The Hospital Service Book and Supplement: Short Services for Use in the Wards of Hospitals and Infirmarys. By the Rev. CHARLES PARKHURST BAXTER, M.A. London: Henry Frowde. 1895.—This is the second edition of a useful abbreviation of the Daily and Communion Services of the Book of Common Prayer, together with a selection of favourite hymns. The supplement is mainly for children's use, and contains also a shortened form of the Ministration of Private Baptism. Prefixed are recommendatory letters from the Bishop of London and the Bishop of Southwark (Suffragan of Rochester).

National Viands à la Mode. By M. de Salis. London: Longmans, Green, and Co.—This little book has been written with the laudable desire of giving English housewives the chance of reproducing in their own homes dishes they may have met with abroad. The recipes have been selected from many countries and offer a pleasant change from the ordinary British solid and uninteresting meal. We must advert unfavourably on the want of accuracy in these recipes. No doubt a sensible cook, aided by a mistress who has seen and eaten of the dishes in question, will do very well; but the average servant is notoriously wanting in common sense, and in many of the recipes no quantities are specified. In the Persian recipes, for instance, it would have been better to say, "Take three pounds of lean mutton," instead of "Take the meat of a leg of mutton." An English leg of mutton weighs anything between 6 lbs. and 25 lbs. However, we doubt not that the book will be useful if used with the limitations we have specified.

Clinical Lectures on the Prevention of Consumption. By WILLIAM MURRELL, M.D., F.R.C.P. London: Baillière and Co.—These lectures were delivered last year at the Westminster Hospital and published in the medical press. They form a simply-written and practical statement of a most important subject, and may be profitably read in conjunction with Dr. Ransome's paper entitled "The Consumption Scare," upon which we commented in a leading article on Feb. 2nd, 1895. Notification, Dr. Murrell considers, is at present impossible, but he lays stress on legislative action as regards public hygiene in reference to phthisis, and on personal efforts for guarding against the dissemination of infectious matter.

The Phonographic Record of Clinical Teaching and Medical Science. No. 5. London: Sir I. Pitman and Sons.—Both as regards the quality and quantity of matter which it contains the present number of the *Record*—a double one—is by far the best that has yet been issued. Dr. James Ritchie contributes a paper on the Therapeutical Pathology of Diphtheria which is a remarkably lucid account of a subject very much in evidence just now. Actinomycosis forms the subject of a clinical lecture by Mr. Edward Ward, who has found potassium iodide productive of good results in its treatment. Mr. E. Nettleship supplies an interesting clinical note on Blinding by Electric Light, and there is a useful note on Belladonna Poisoning by Mr. Raymond Johnson. Dr. Julius Dreschfeld and Mr. R. J. Godlee also contribute to the same number.

La Pratique de la Sérothérapie. By Dr. H. GILLET. Paris: J. B. Baillière et Fils. 1895.—This book gives an account of the treatment of diphtheria by the methods of serum therapeutics, intubation, and tracheotomy. The account of the serum treatment is the most interesting part of the book, and its history, modes of preparation, administration, and effects are all made clear, and the explanation is aided by several diagrams and temperature charts. Very full statistics are given, which mostly tend to show the advantages of the serum treatment, but at the same time all sides of the subject are dealt with, and we find a chapter which deals with all the objections—real or supposed—which have been urged against this method of treatment. The chapters on intubation and tracheotomy give accounts of the histories and methods of performing the operations, together with some comparative statistics. The book is very clearly printed and contains numerous illustrations.

New Inventions.

A NEW FORM OF UTERINE DILATOR.

I WISH to draw attention to a new form of uterine dilator that Messrs. Down Brothers have made for me with great care, and which in my own hands and those of my friends has proved a very useful instrument. Briefly, the construction is as follows. Each dilator is seven inches in length, is made of metal electro-plated, and is hollow and conical. They are a variety of Hegar's dilators, and the sizes are on Hegar's scale; but, unlike his instruments, which are too numerous, advance in complete sizes, and are not so certainly kept clean as a metal instrument. Mine are conical, each dilator covering three sizes Hegar in the first inch and a half and a fourth size in the next inch. My No. 1 starts at 3 Hegar and ends at 6 Hegar, within two inches and a half of the point. No. 2 runs from 4 to 7 Hegar. My last, No. 16, from 19 to 22 Hegar, a size large enough for most purposes. No. 1 is not too large to start with, and when one dilator has passed the next is easily received and used. Messrs. Down have at my request stocked this form of dilator with a slight curve, to meet the predilections of most gynaecologists; but the set I use are perfectly straight, and I have never had the slightest difficulty with them even in cases where I most feared it, and never any of that trouble which one often experiences with the larger size Hegar, which, advancing in complete sizes, is sometimes refused by the cervix.

My apology for troubling you must be that the difficulty I had in finding a dilator reasonably cheap, convenient, and useful for immediate dilatation must have been felt by others whom the usual uterine dilators do not satisfy. I hope the instrument here described will prove of service to such.

G. A. HAWKINS-AMBLEY, F.R.C.S. ED.

THE LANCET.

LONDON: SATURDAY, MAY 4, 1895.

WE have already succinctly set forth most of the results at which the Royal Commission on Opium has arrived.¹ In the opinion of many no necessity had, in reality, been shown for any such inquiry at all, but we think the Government of this country and India are to be congratulated on the fact that it has taken place and that the matter has been fully and impartially considered. We may fairly hope, now that it has been disposed of to the satisfaction of all candid people, that the result will be final, or that, at any rate, it will not come again within "the range of practical politics" for a very long time. The evidence adduced carried conviction to eight out of the nine members forming the Commission—even Mr. A. PEASE, who is supposed to have started with an opposite bias, having been converted. It may be taken as settled that the use of opium in India is extensively common and is attended with a remarkably small amount of injury; that the drug is regarded as a sort of domestic comfort; and that it is practically quite harmless as compared with the use and abuse of alcohol in other countries. There are, of course, cases in which the abuse of opium leads to disastrous consequences, but these are comparatively very rare. The habit of opium-eating in India does not appear to obtain such mastery over a man's nature and to be attended with such an amount of crime and lamentably degrading results as intemperate habits in regard to alcohol do elsewhere; and the prohibition of the use of opium is not only uncalled for, but is, moreover, impracticable and would lead to infinitely greater mischief if it were followed, as it in all probability would be, by the introduction and increased consumption of alcohol among the natives of India. It must be within the knowledge of a large number of medical officers, who have served or are now serving in India, how commonly opium is used in some native regiments; but how very few indeed of those medical officers have ever witnessed any of those evil effects which the anti-opium *fac-dists* declare to be so common, and of which they have drawn such graphic and terrible but imaginary pictures.

Sir WILLIAM ROBERTS, M.D., F.R.S., has set forth his views on the general features and the medical aspects of the question in a separate memorandum annexed to the official report of the Commission. This memorandum will be read with much interest. Sir WILLIAM ROBERTS alludes to the fact, to which we adverted in our article on the report of the Commission in THE LANCET of last week, that the use of opium is only one manifestation of a practice common to all human communities. Articles are consumed for their stimulating, restorative, or soothing qualities, and not because they possess nutritive properties or are articles of food. That the needs and requirements of life create a craving for such articles is abundantly shown by the habits and practices of different races and nations. Opium takes a position intermediate between alcohol and tobacco; but the habitual and excessive use of alcohol is

followed by special organic changes that can be traced both during life and after death, and this is not the case with either opium or tobacco. Sir WILLIAM ROBERTS thinks that the number of opium-eaters in India is likely to be under- rather than over-estimated; that the opium habit is widely disseminated all over India; and that, as it may be practised for years without exciting suspicion, the estimates given of the ratio of opium-eaters to population must be taken with great reserve. He dwells upon the greater tolerance for opium among the natives of India as compared with Europeans, and cites the evidence of Surgeon-Lieutenant-Colonel CROMBIE as regards the very different effect of opium on native and English infants in support of the view that this enhanced tolerance on the part of the native of India is apparently congenital. Many of our Anglo-Indian readers will possibly recall here the chapter "Baby in Partibus" in that interesting little book, "Twenty-one Days in India," by the late GEORGE ABERNETHY-MACKAY, in which the effect of opium surreptitiously administered by the ayah in charge of a European infant is pathetically sketched. Sir WILLIAM ROBERTS cites some illustrations of the large quantities of opium occasionally consumed, but he says that the average tolerance of natives of India, judging from the practice of opium-eaters, appears to range from four to twelve grains of opium per day. There are several interesting points that have yet to be investigated in regard to the use and the natural or acquired tolerance of opium on the part of the natives of India. We have heard that on field service—in such expeditions as, for instance, that for the relief of Chitral at the present time—the Mahomedan troops use opium with much apparent benefit under conditions involving great wear and tear of tissue, and where the fatigue is great and the food-supplies are small or coarse, irregular, and uncertain.

The late Mr. SKEY long ago pointed out the beneficial effect that followed the use of opium in indolent ulcerations affecting aged and enfeebled folk; and Mr. GEORGE POLLOCK has called attention to the remarkable benefit to be derived from the same drug in certain forms of sloughing and destructive disease of the mouth in children. There is evidently still much to be learned about the use of opium in its effect on the nervous system and the nutritive changes of tissue.

LADY PRIESTLEY'S article in the *Nineteenth Century* on "The Penalties of Ignorance" is worthy of perusal by every intelligent householder. It cannot, indeed, be said that the facts therein presented contain any novelty for the members of the medical profession, but they are marshalled with skill and effect, and their general dissemination would undoubtedly be most salutary. It is always depressing to reflect how far in matters connected with personal, domestic, and national hygiene and sanitation practice lags behind knowledge, and hence we should welcome every well-directed effort to bring to bear upon the public the latest results of science. Our profession cannot escape a considerable degree of responsibility in this matter. The press, popular lectures, and other agencies may do much to spread knowledge, but the family physician remains the usual court of appeal in matters that touch health at any point, and his deliverance is generally final. Hence, he must not disdain many

¹ THE LANCET, April 27th, page 1078.

things that may seem a little out of his province, such as the state of the drains, the cistern, the larder, the meat safe, and the like. Disease may lurk in each or all of these, and it would be entirely unworthy of scientific medicine to treat the results of domestic ignorance or carelessness without endeavouring to strike at their causes. As we were recently reminded by Professor ZIEMSEN, medicine is now in the "etiological stage," and there never was a time when the public were quicker to recognise the importance of finding out and removing the sources of disease rather than attempting simply to palliate its effects. The ideas that are now spreading widely among the public are sound and valuable so far as they go—such, for example, as the importance of cleanliness, fresh air, pure water, pure milk, and unadulterated and wholesome food—but they are somewhat vague, and well-meaning but not fully instructed persons much need to be taught how the commonplaces and truisms of hygiene can be transformed into sound and salutary practice. To this end articles like those of Lady PRIESTLEY are valuable contributions. The writer begins by recalling the horrors of hospital practice when sepsis was unknown and unpractised, and, describing an old and insanitary hospital used at the time of the Franco-Prussian war, says with grim truth that "the wounded were carried in hundreds from the comparative safety of the battlefield to this sanctuary of death." Visiting the same hospital after the lapse of some years, the writer found that "the epoch had made its mark. Throughout the corridors a whirlwind of air swept day and night, bath-rooms were established, the wards were untainted; silence, order, and cleanliness—scientific cleanliness—prevailed." Lady PRIESTLEY continues: "Since PASTEUR in the course of his chemical researches dragged the long-hidden cause of disease into light, and opened our eyes to a hitherto unsuspected law of nature, we can no more get rid of the newly revealed facts than we can stop the rotation of the earth. And yet this knowledge, so important in housekeeping, so useful to those who are responsible for the health of others, and which so closely concerns us all, forms no part in the general education of the people. The precious key has been given to us, but so far as domestic life is concerned the gates of knowledge remain closed." The writer's aim is to impress upon every woman who has charge of a household that PASTEUR's discoveries concern her vitally; that the causes which produce disease and those which impair the wholesomeness of food are analogous; that in both cases the cause is frequently a bacterium which requires warmth and moisture for its growth; and that cold, fresh air, ventilation, and the avoidance of damp rob many, perhaps most, of these germs of their capacity for mischief. Visiting a larder in a fine old English mansion where recent scientific teaching had not penetrated she "was deeply interested to find herself in the midst of surroundings which had become more or less familiar to her in visiting various bacteriological laboratories in different parts of the world. It was certainly most fascinating to discover Dame Nature at her work, fulfilling her rôle undisturbed in this most disapproved fashion. Here in the homely larder Nature was having her way unhindered by the scientific mind which in the laboratory keeps all things under control."

Other dangers of a like nature are passed in review by the

writer. Milkshops in close conjunction with filthy mews, poulterers' shops with live rabbits fouling the atmosphere, meat exposed to all the exhalations from public thoroughfares—such are some of the commonest errors, but there are many others of a like nature. No country excels Great Britain in the fine quality of the meat offered for sale, but we are still far from fully realising the necessary conditions for preserving this meat in a perfectly sound and wholesome condition. The results are much waste of good food and much preventable disease. Cold storage is justly commended as one of the best means of averting all this waste and danger to health, and it is satisfactory to know that, long established as an ordinary practice in America, it is becoming acclimatised amongst ourselves. "Cold," as Lady PRIESTLEY says, "is one of the simplest and least objectionable antiseptics that can be used in the case of food, and must not be confused with freezing, which interferes more or less with the flavours of meat and game. In applying cold it is sufficient to preserve exactly the amount of chill that will suspend the vitality of the putrefactive organisms. Meat that is brought from New Zealand and Australia is frozen owing to the distance it has to come, but meat brought from America is simply chilled." The writer laments that the English law is so lax regarding the destruction of presumably diseased meat. The meat inspector is obliged to take each case before a magistrate and is liable to an action for damages if the magistrate takes a different view from his regarding the soundness of the meat. This is a very difficult question, and we are by no means clear that the law on this subject is to be condemned. It is unlikely that any intelligent magistrate will set aside the evidence of an expert, unless for very strong reasons. We should, however, entirely approve of means being taken to safeguard meat inspectors from frivolous actions for damages. The state of farms and farm buildings is passed in review by the writer, and the general neglect of cleanliness and ventilation animadverted upon. We are glad to think that much progress is at present going on amongst us with regard to these matters. Clean and well-ventilated farm buildings mean healthy cattle, healthy cattle mean pure milk, and pure milk means healthy children. Lady PRIESTLEY appositely quotes a remark from one of Sir WILLIAM JENNER's essays, and with this quotation we conclude our notice of a very interesting, valuable, and timely article. "Can we wonder," says Sir WILLIAM JENNER, "that rickets is prevalent among the poor of London? Can we fail to wonder that geography, history, and crotchet work form such large items in the instruction imparted at our national schools and the doctrines of life so small an item? Let the girls there educated be taught that Constantinople is the capital of Turkey if it is of any advantage for them to know it, but let them also learn how to dress, feed, nurse, and lodge an infant so that it may run a fair chance of not swelling the amount of that truly awful column in the Registrar-General's return—'Deaths under one year.'"

THE recent disclosures of the horrible treatment of a woman in Ireland for the purpose of expelling a witch who was supposed to be the temporary tenant of her body are

so repulsive and revolting to educated people of the present day that it is difficult to realise that a belief in the relation of witchcraft to disease was quite general in this country up to a century or two ago. Not only by the unlettered but by the highest intellects in the land witchcraft was regarded as so well established as to be unquestionable. Sir MATTHEW HALE, Sir THOMAS BROWNE, and, if we mistake not, Lord BACON, all gave most positive utterances on the subject. In the middle of last century a captain of the City Guard was burnt in the Grassmarket in Edinburgh on the charge of being a "warlock" or wizard, and the frequency of executions in other countries in the Middle Ages may be imagined from the estimate (no doubt exaggerated) which SPRENGER gives of seven millions, as the number of those executed by judicial process in consequence of the Bull of INNOCENT VIII. making witchcraft a capital offence. The ways in which wizards or witches were supposed to interfere with the well-being of other people were many. They were supposed to prevent speculations becoming remunerative, to interrupt the course of true love, or to impoverish a man by sending a blight on his crops or a murrain among his cattle; and, further, they had the power, it was believed, of inducing disease and causing death in any individual whom they might select for their malevolent purpose. The diseases which seem especially to have been considered as due to such influences were convulsive nervous diseases, wasting diseases, and mental defect or paralysis in children. The revenue of a witch was largely made up by presents from parents to gain the goodwill of this powerful and dreaded person and so avert ill from them and theirs. In other cases they were paid to bring evil upon the donor's enemies, and it is to be feared that in these cases poison was not infrequently employed.

But, returning to more strictly medical cases, we can see a good deal of ground for the popular belief in the presence of unseen agencies. Taking convulsive affections, such as hysteroid or epileptic fits, who that has watched them and seen a frail girl thrown into strange contortions, struggling with sufficient force to tax the strength of several men, can fail to understand the almost universal idea that the bodies of such patients were "possessed" by some powerful mysterious spirit? So again when a girl, who previously was dull and stupid, in a hysterical fit recites with appropriate gesture and strikes difficult emotional attitudes with marvellous accuracy, feats which she cannot accomplish in her ordinary condition, what wonder that bystanders imagine that it is not the patient who is reciting, singing, and acting, but some clever spirit who has taken possession of her?

In various wasting diseases, such as diabetes, cancer, and tuberculosis, in spite of the patient eating freely, if not ravenously, the food does no good, and the patient gets rapidly thinner. The explanation by spirit possession must seem to primitive minds an obvious one, the spirit stealing the food which the patient swallows for his own nourishment. Such ideas of possession are to be found among all the lower and uneducated races, and no doubt were entertained by our ancestors and have been handed down by word of mouth to many of their descendants to-day. But in not very distant times this idea of possession underwent a further development.

Not only was a strange spirit introduced into the body, but the real occupant of the body was carried away and kept prisoner by the fairies, who were under the power of the witches. Later, the body as well as the spirit was supposed to be substituted, and what is called "a changeling" left in its place. Usually this change took place in the cradle, but occasionally, as in the recent case of BRIDGET CLEARY, an adult was supposed to be similarly changed. This belief in changelings can be traced in many old Celtic legends, particularly Irish ones,¹ and is found also in SHAKESPEARE. HENRY IV. is lamenting over the follies of his son and contrasting him unfavourably with HOTSPUR, the Duke of NORTHUMBERLAND'S son, and says:

"O, that it could be proved
That some night-tripping fairy had exchanged
In cradle clothes our children as they lay."²
